Subject: Sutterville Road Access Feasibility Study – Draft Report P07005.08

Dear Samar:

Dowling Associates is pleased to submit this revised draft report for the Sutterville Road Access Feasibility Study. The report documents our analysis of baseline and cumulative conditions.

Sincerely,

Dowling Associates, Inc.

List of Figures

Overview

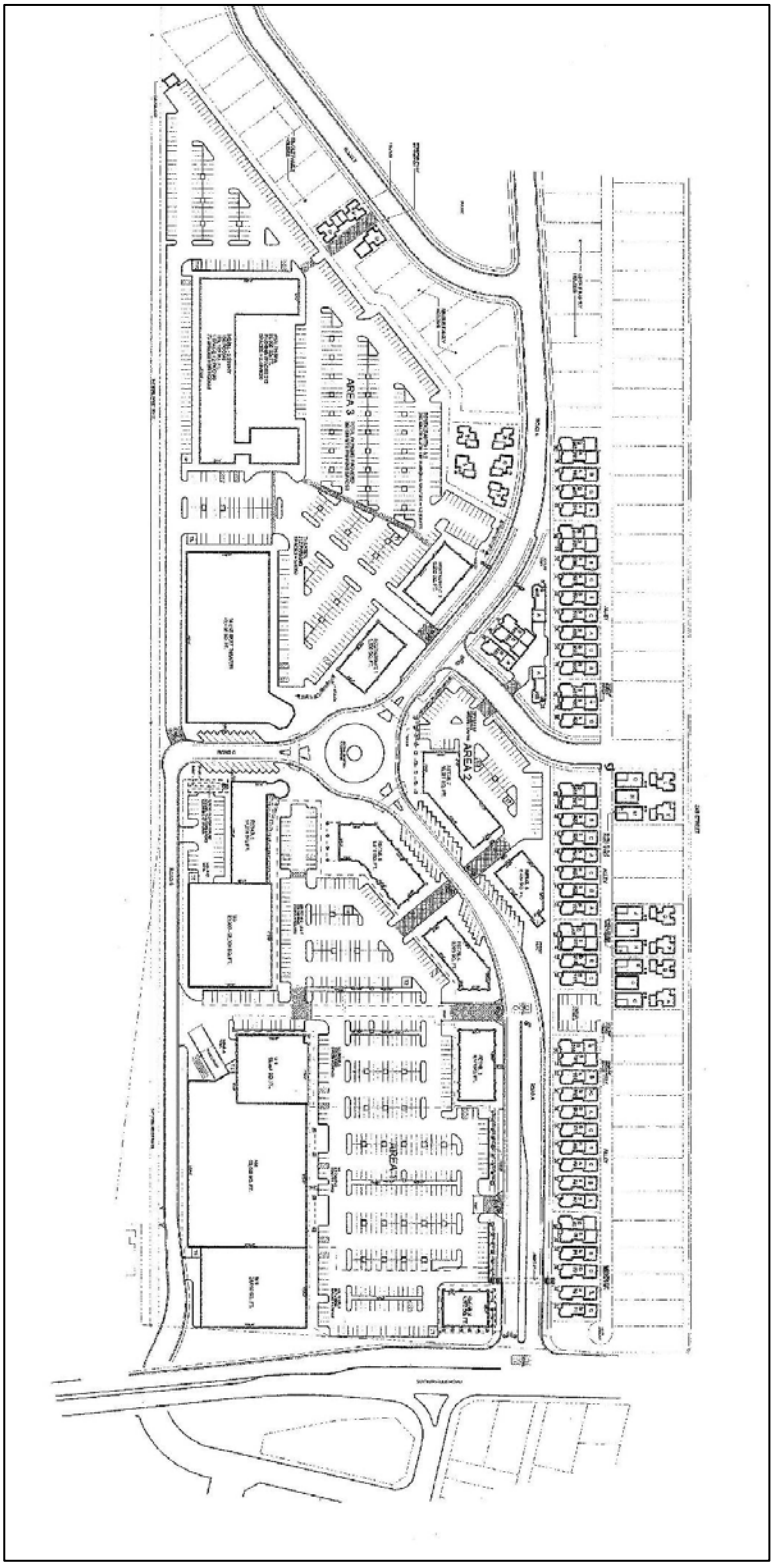
Sutterville Road is a two-mile long east-west roadway that runs from I-5 near Riverside Boulevard east along the southern edge of Land Park to Freeport Boulevard. It then resumes about 1,200 feet north as a four-lane arterial road to Franklin Boulevard where it continues as 12th Avenue. A bridge on Sutterville Road passes over the Union Pacific railroad track. The study area is located to the immediate east of the overpass. Sutterville Road carried an average daily traffic volume of approximately 28,000 vehicles in 2007 in the study area.

A center median divides Sutterville Road in the study area. Access between the north side and the south side of the roadway is provided by bypass loop ramps that traverse under Sutterville Road as shown in Figure 1. The bypass ramp on the north side of Sutterville Road is located in the proposed Curtis Park Village project site and is to be reconfigured as a part of that project (Curtis Park Village EIR, May 2008). After the implementation of Curtis Park Village, vehicles desiring to travel from the south to westbound Sutterville Road would have to pass through Curtis Park Village upon exiting from the underpass and enter Sutterville Road via the proposed Road A. Conversely, vehicles desiring to travel from westbound Sutterville Road to the south would enter Road A, pass through Curtis Park Village before entering the underpass. A proposed site plan of the Curtis Park Village project is shown in Figure 2.

The purpose of this study is to analyze the feasibility of two potential alternatives that would provide direct street connections between the north side and the south side of Sutterville Road. The effects of the alternatives on the adjacent street system are analyzed and mitigation measures are recommended. This doesn't include any geometric design or cost estimation.

Figure 1 Aerial Photo of Study Area

Figure 2 Proposed Curtis Park Village Site Plan



Project Alternatives

Two access alternatives were developed with guidance from City staff. Both alternatives focused on Road A, the main Curtis Park Village access point on the north side, and West Pacific Avenue on the south side of Sutterville Road. The two alternatives are described below:

Single Intersection. The Single Intersection Alternative would realign West Pacific Avenue to connect to Sutterville Road directly across from Road A and provide a standard four-legged signalized intersection.

Split Intersections. The Split Intersections Alternative would provide two signalized T-intersections at West Pacific Avenue and at Road A. The two intersections would be coordinated under one traffic signal controller as if it were one intersection. This alternative allows the existing alignment of West Pacific Avenue to remain.

Graphic presentations of the two alternatives are shown in Figure 3 and Figure 4. Under both alternatives, the existing underpass will remain as envisioned in the Curtis Park Village EIR and provide an alternative linkage between the south and the proposed Curtis Park Village development.

Traffic Analysis

This study focused on the effects of the proposed alternatives on the Sutterville Road intersections of Road A and West Pacific Avenue in the morning (AM) and afternoon (PM) peak hours under baseline and cumulative conditions. The alternative's potential impacts on nearby roadways will be qualitatively discussed. A brief description of each of the roadways is provided below:

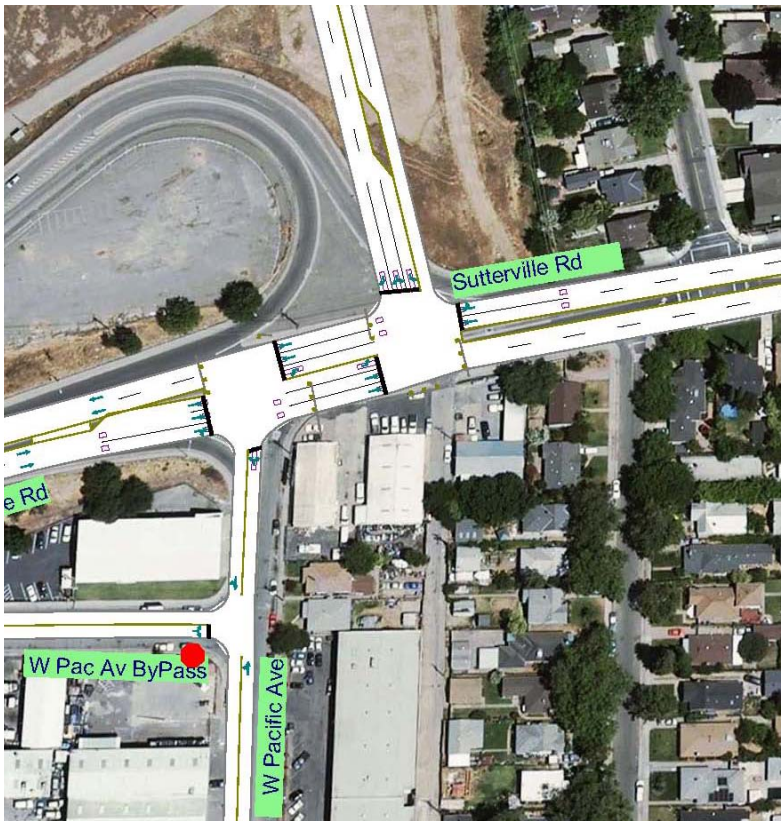
Sutterville Road is a four-lane divided arterial between the railroad overpass and Jeffrey Avenue.

West Pacific Avenue is a two-lane local road that operates between Sutterville Road and 18th Avenue. It serves a mix of primarily industrial land uses north of Wilmington Avenue and residential land uses south of Wilmington Avenue.

Deeble Street is a two-lane local road that runs from West Pacific Avenue Bypass through an industrial area to terminate in the residential neighborhood south of Wilmington Avenue.

Figure 3 Single Intersection Alternative

Figure 4 Split Intersections Alternative



West Pacific Avenue Bypass is a two-lane road that connects West Pacific Avenue to Deeble Street on the north and south sides of Sutterville Road.

Jeffrey Avenue lies on the east of West Pacific Avenue and extends from Sutterville Road south to 18th Avenue. It then resumes 75 yards west and continues south to terminate at Lew Way. Residential land uses are found along the full length of the two-lane local roadway.

Wilmington Avenue runs parallel to and south of Sutterville Road between Deeble Street and Franklin Boulevard. In the study area, it has two travel lanes and serves as a divider between primarily industrial and residential land uses.

The traffic volumes used in this study were derived from data from the Curtis Park Village EIR. The development assumptions and mitigation measures identified in the Curtis Park Village EIR were assumed to be in place.

Both proposed project alternatives assume that all existing loop ramp traffic that is not generated by Curtis Park Village will be diverted onto Sutterville Road or West Pacific Avenue through the study intersection(s).

Analysis Methodology

"Levels of service" describe the operating conditions experienced by motorists. Level of service is a qualitative measure of the effect of a number of factors, including speed and travel time, traffic interruptions, freedom to maneuver, driving comfort and convenience. Levels of service are designated "A" through "F" from best to worst, which cover the entire range of traffic operations that might occur. Level of Service (LOS) "A" through "E" generally represent traffic volumes at less than roadway capacity, while LOS "F" represents over capacity and/or forced flow conditions.

The City of Sacramento General Plan (October 1987) outlines the goals and policies that coordinate the transportation and circulation system with planned land uses. The General Plan (Goal D, Street and Road section) identifies LOS C as the goal for City's local and major street system except at freeway ramp intersections, where the goal is LOS D.

The intersection level of service analysis was performed using the Synchro traffic impact analysis software package.

Signalized Intersections Analysis

Signalized intersection analyses were conducted using the operational methodology outlined in the Highway Capacity Manual (Transportation Research Board, Washington, D.C., 2000, Chapters 10 and 16). This procedure calculates an average stopped delay per vehicle at a signalized intersection, and assigns a level of service designation based upon the delay. The method also provides a calculation of the volume-to-capacity (v/c) ratio of the critical movements at the intersection. Table 1 shows level of service criteria for signalized intersections.

Table 1
Level Of Service Criteria – Signalized Intersections

Level of Service (LOS)	Average Delay (seconds/vehicle)	Description
A	≤ 10	Very Low Delay: This level of service occurs when progression is extremely favorable and most vehicles arrive during a green phase. Most vehicles do not stop at all.
B	>10 and ≤ 20	Minimal Delays: This level of service generally occurs with good progression, short cycle lengths, or both. More vehicles stop than at LOS A, causing higher levels of average delay.
C	> 20 and ≤ 35	Acceptable Delay: Delay increases due to only fair progression, longer cycle lengths, or both. Individual cycle failures (to service all waiting vehicles) may begin to appear at this level of service. The number of vehicles stopping is significant, though many still pass through the intersection without stopping.
D	> 35 and ≤ 55	Approaching Unstable Operation/Significant Delays: The influence of congestion becomes more noticeable. Longer delays may result from some combination of unfavorable progression, long cycle lengths, or high volume / capacity ratios. Many vehicles stop, and the proportion of vehicles not stopping declines. Individual cycle failures are noticeable.
E	> 55 and ≤ 80	Unstable Operation/Substantial Delays: These high delay values generally indicate poor progression, long cycle lengths, and high volume / capacity ratios. Individual cycle failures are frequent occurrences.
F	> 80	Excessive Delays: This level, considered unacceptable to most drivers, often occurs with oversaturation (that is, when arrival traffic volumes exceed the capacity of the intersection). It may also occur at nearly saturated conditions with many individual cycle failures. Poor progression and long cycle lengths may also contribute significantly to high delay levels.

Source: Transportation Research Board, *Highway Capacity Manual*, Washington, D.C., 2000, pages 10-16 and 16-2.

Unsignalized Intersections Analysis

Stop sign controlled intersections were analyzed utilizing the methodology outlined in the Highway Capacity Manual (Transportation Research Board, Washington, D.C., 2000, Chapters 10 and 17). This methodology determines the Level of Service by calculating an average total delay per vehicle for each controlled movement and for the intersection as a whole. A LOS designation is assigned based upon the average control delay of all movements. Table 2 presents the relationship of total delay to level of service for stop controlled intersections.

Table 2
Level of Service Criteria Unsignalized Intersections

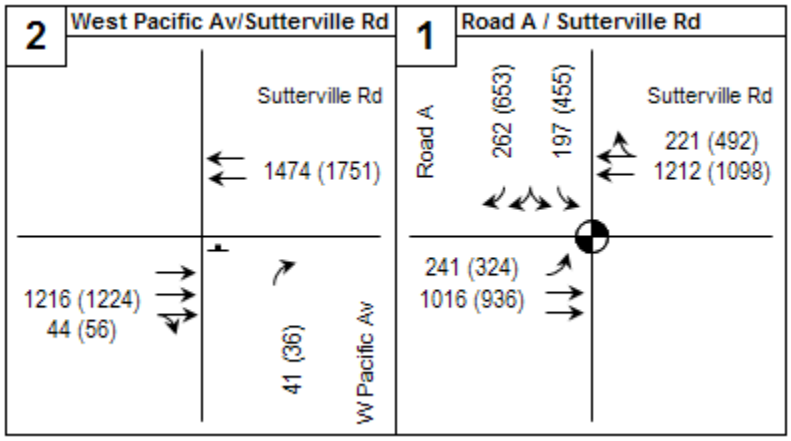
Level of Service	Average Control Delay (seconds/vehicle)
A	0 - 10
B	>10 - 15
C	>15 - 25
D	>25 - 35
E	>35 - 50
F	>50

Source: Transportation Research Board, *Highway Capacity Manual*, Washington, D.C., 2000, pages 10-16 and 16-2.

Baseline Conditions

The performance of the traffic operations under baseline conditions was established to serve as a basis to evaluate the effects of the proposed alternatives on the roadway network. The baseline traffic volumes include estimated traffic on the existing roadway network plus projected vehicle trips that would be generated by future developments that are pending or have been approved by the City, such as the Curtis Park Village development. The baseline No Project traffic volumes and lane geometries at the two study intersections are shown in Figure 5.

Figure 5 Intersection Volumes and Geometries – Baseline No Project Conditions



Baseline peak hour traffic volumes and lane geometries at the study intersections under the Single Intersection Alternative and the Split Intersection Alternative are shown in Figure 6 and Figure 7, respectively.

Figure 6 Intersection Volumes and Geometries - Single Intersection Alternative

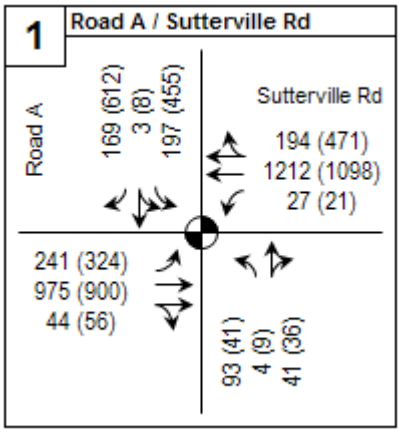


Figure 7 Intersection Volumes and Geometries - Split Intersections Alternative

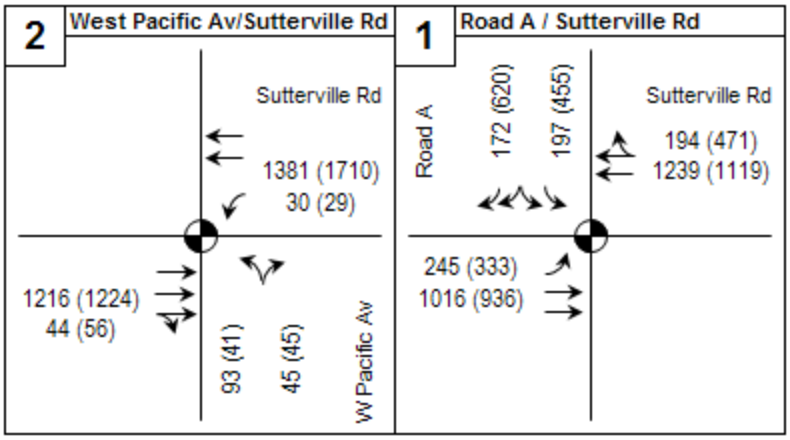

Baseline Intersection Operations

The baseline AM and PM peak hour intersection level of service results are presented in Table 3.

Table 3
Level of Service – Baseline Conditions

		No Project		Single Intersection Alternative		Split Intersections Alternative	
Intersection	**Peak Hour**	**Delay**	**LOS**	**Delay**	**LOS**	**Delay**	**LOS**
Road A / Sutterville Road	AM	17.4	B	**40.3**	**D**	18.8	B
	PM	**39.4**	**D**	**83.7**	**F**	**71.5**	**E**
West Pacific Avenue/Sutterville Road	AM	0.2	A			7.6	A
	PM	0.1	A			9.1	A

Note:
Delay denotes average vehicle delay in seconds
LOS denotes level of service

If neither of the project alternatives is implemented, the intersection of Road A and Sutterville Road would operate at LOS D with over 39 seconds of average vehicle delay in the PM peak hour. The 95th percentile queue length for the single-lane eastbound left-turn movement is 390 feet and for the two-lane southbound left-turn movement is 248 in the PM peak hour.

With the implementation of the Single Intersection Alternative and the Split Intersections Alternative, the results indicated that the Road A and Sutterville Road intersection would operate at LOS F and LOS E under the two alternatives in the PM peak hour, respectively. The intersection would also degrade to LOS D under the Single Intersection Alternative in the AM peak hour.

The long eastbound and southbound left-turning queues at the Road A intersection may also impact traffic operations as the queues may extend beyond the storage bays and block the through traffic lanes. As shown in Table 4, the issue with storage capacity is particularly acute in the PM peak hour.

Table 4
Left-turning Movements 95th Percentile Queue Lengths at the Road A intersection – Baseline Conditions (in feet)

Approach	Peak Hour	No Project	Single Intersection Alternative	Split Intersections Alternative	Maximum Available Capacity[1]
Eastbound	AM	239	391	324	450[2]
	PM	390	**597**	**482**	450[2]
Southbound	AM	76	100	146	300[3]
	PM	248	253	**418**	300[3]

[1] Based of rough measurements of available site plans or aerial photos

[2] Estimated distance between the Sutterville Road Underpass and Road A less transition distance; other considerations may shorten available storage capacity.

[3] Estimated maximum distance available for SB left-turn pocket based on Curtis Park site plan dated March 12, 2008.

While not reflected in the level of service results, a potential operational and safety issue has been identified for the Split Intersections Alternative. Vehicles traveling from Curtis Park Village to the south or vice versa via the study intersections on Sutterville Road would have to cut across two travel lanes within a short distance to reach the left-turn pocket upon making the right turn. Blockage of the through lanes or increased safety hazard may result with such a

maneuver. However, the number of vehicles making such a maneuver is likely to be few because an alternative route is provided through the underpass.

Baseline Intersection Mitigation Measures

Improvement measures have been identified to lessen the impacts of the proposed project alternatives at the study intersections. These improvement measures and the improved outcomes are described below.

For the Single Intersection Alternative, implementing the following measures would improve the Road A/West Pacific Avenue and Sutterville Road intersection to LOS C in both the AM and PM peak hours with average delays of 22.1 seconds and 34 seconds, respectively.

- Add one eastbound left-turn lane to provide two left-turn lanes, one through lane and one through-right shared lane;
- Add one dedicated westbound right-turn lane. This improvement has been identified as a mitigation measure under cumulative conditions in the Curtis Park Village EIR;
- Optimize traffic signal phase split.

The 95th percentile left-turn queue would be 137 feet for the eastbound approach and 434 feet for the southbound approach in the PM peak hour. The project should provide sufficient storage capacities wherever feasible.

For the Split Intersections Alternative, implementing the following measures would improve the Road A and Sutterville Road intersection to LOS B (14.6 seconds of delay) in the AM peak hour and LOS C (32.4 seconds of delay) in the PM peak hour. The operations at the West Pacific Avenue and Sutterville Road intersections would also improve.

- Re-stripe the southbound lanes at the Road A intersection to provide one right-turn lane and two left-turn lanes;
- Add one eastbound left-turn lane to provide two left-turn lanes; one through lane and one through-right shared lane at the Road A intersection; and add one eastbound through lane at the West Pacific Avenue intersection as an extended left-turn pocket.
- Provide signage to direct vehicles traveling between Curtis Park Village and the south to use the Sutterville Road underpass.

The 95th percentile left-turn queue for the Split Intersections Alternative would be 211 feet for the eastbound approach and 269 feet for the southbound approach. The project should provide sufficient storage capacities wherever feasible.

Cumulative Conditions

The cumulative conditions analysis focuses on year 2027 conditions. As with baseline conditions, the traffic volumes were derived from the Curtis Park Village EIR and mitigation measures identified in that study are assumed to be implemented. Further, the baseline mitigation measures described above are also assumed to be in place for the analysis of cumulative conditions.

The traffic volumes and lane geometries for the Cumulative No Project, Single Intersection Alternative, and Split Intersection Alternative are presented in Figure 8, Figure 9, and Figure 10, respectively.

Figure 8 Cumulative Intersection Volumes and Geometries –No Project Conditions

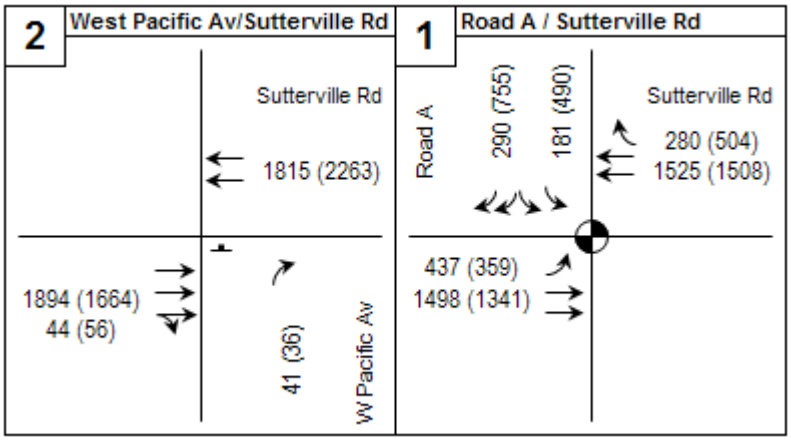

Figure 9 Cumulative Intersection Volumes and Geometries - Single Intersection Alternative

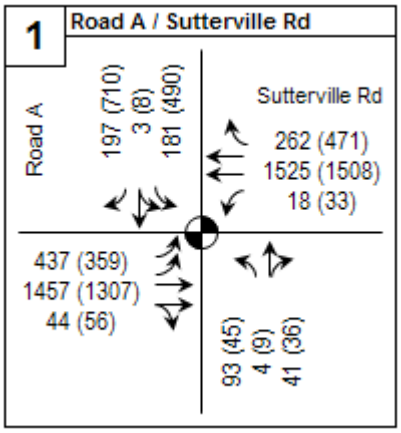

Figure 10 Cumulative Intersection Volumes and Geometries - Split Intersections Alternative

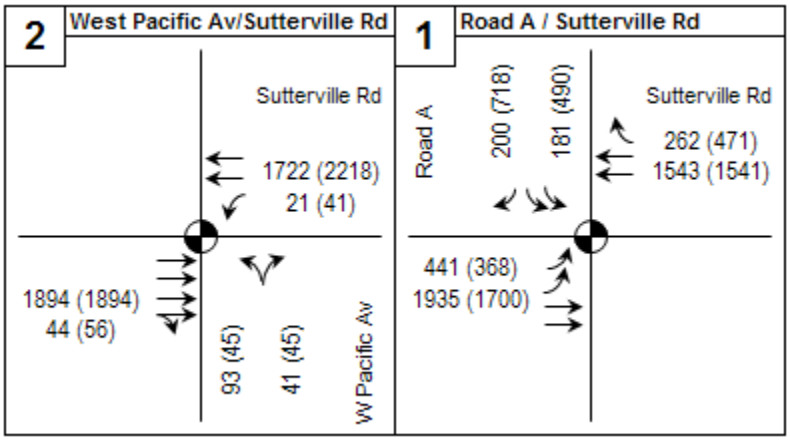

Cumulative Intersection Operations

The intersection level of service results are shown in Table 5. The Road A and Sutterville Road intersection would operate at LOS D under the No Project scenario in the PM peak hour. The 95th percentile left-turn queue would exceed possible storage capacity in the AM peak hour for both the eastbound and southbound approaches.

Table 5
Level of Service – Cumulative Conditions

		No Project		Single Intersection Alternative		Split Intersections Alternative	
Intersection	**Peak Hour**	**Delay**	**LOS**	**Delay**	**LOS**	**Delay**	**LOS**
Road A / Sutterville Road	AM	28.6	C	**44.6**	**D**	17.6	B
	PM	**35.7**	**D**	**49.9**	**D**	28.0	C
West Pacific Avenue/Sutterville Road	AM	0.2	A			8.2	A
	PM	0.1	A			12.6	B

Note:
Delay denotes average vehicle delay in seconds
LOS denotes level of service

Under the Single Intersection Alternative, the Road A intersection would operate at LOS D in both the AM and PM peak hours. Under the Split Intersections Alternative, both the Road A and the West Pacific Avenue intersections would operate within City standards during the peak hours.

As shown in Table 6, the 95th percentile left-turn queue lengths at the Road A and Sutterville Road intersection may be adequately accommodated by the maximum available storage capacity.

Table 6
Left-turning Movements 95th Percentile Queue Lengths – Cumulative Conditions (in feet)

Approach	Peak Hour	No Project	Single Intersection Alternative	Split Intersections Alternative	Maximum Available Capacity[1]
Eastbound	AM	509	315	262	450[2]
	PM	443	286	224	450[2]
Southbound	AM	762	92	107	300[3]
	PM	286	273	293	300[3]

[1] Based of rough measurements of available site plans or aerial photos

[2] Estimated distance between the Sutterville Road Underpass and Road A less transition distance; other considerations may shorten available storage capacity.

[3] Estimated maximum distance available for SB left-turn pocket based on Curtis Park site plan dated March 12, 2008.

Cumulative Mitigation Measures

By optimizing the traffic signal phase split, the impacts of the Single Intersection Alternative would be lessened. The level of service at the Road A/West Pacific Avenue and Sutterville Road intersection would improve to LOS C in the AM peak hour but would remain at LOS D in the PM peak hour with a decrease in average delay by 8.4 seconds to 41.5 seconds.

Roadway Impacts

The potential impacts of the two project alternatives on the study roadway segments are discussed in this section.

The project alternatives have little effect on the roadway network beyond the study area, which is defined by the railroad underpass to the west, Jeffrey Avenue to the east, Wilmington Avenue to the south and Sutterville Road to the north. Even within the boundaries, the potential changes in traffic volumes on the study roadways are relatively minor.

West Pacific Avenue

The largest change would be seen on West Pacific Avenue, where vehicles would be diverted from the underpass. Under the baseline conditions, northbound traffic would increase by 93 (41) vehicles for both project alternatives during the AM (PM) peak hours; while southbound traffic would increase by 27(21) vehicles and 30(29) vehicles for the Single Intersection and the Split Intersections Alternatives, respectively. Under the cumulative conditions, northbound traffic would increase by 93(45) vehicles for both alternatives; while southbound traffic would increase by 18(33) vehicles and 21(41) vehicles for the Single Intersection and the Split Intersections Alternatives, respectively.

Sutterville Road

The only changes in traffic volumes on Sutterville Road occur between the intersections of Road A and West Pacific Avenue. The Single Intersection Alternative would result in an increase of 3(20) eastbound vehicles in the AM(PM) peak hours under both baseline and cumulative conditions. The Split Intersections Alternative would cause the westbound volumes to decrease by 63 (12) vehicles in the AM(PM) peak hours and the eastbound volumes to increase by 4(9) vehicles during the same periods.

Deeble Street

The traffic on Deeble Street between Sutterville Road and Wilmington Avenue would likely decline as a result of the project alternatives. With fewer vehicles utilizing the underpass, the diverted traffic not destined for locations on Deeble Street could be expected to utilize West Pacific Avenue.

Jeffrey Avenue

The traffic on Jeffrey Avenue between Sutterville Road and Wilmington Avenue is relatively light. The 2005 counts showed 10 northbound and 13 southbound vehicles during the AM peak hour and 15 vehicles on each direction during the PM peak hour. While a few of the northbound vehicles intended to head west on Sutterville Road may shift to West Pacific Road, it is unlikely the amount would be significant since the underpass option has always been available.

Wilmington Avenue

The reduction in traffic on Deeble Street would have a direct effect on Wilmington Avenue. The traffic on the segment between Deeble Street and West Pacific Avenue could be expected to decrease relatively. No other significant change on Wilmington Avenue is anticipated.

Conclusion

The advantages and disadvantages of the two access alternatives are summarized below.

Single Intersection Alternative

The advantages of the Single Intersection Alternative are:

- Standard 4-legged configuration that motorists, pedestrians and other users are familiar with;
- Few operational issues that would result in hazardous maneuvers.

The disadvantages of the Single Intersection Alternative are:

- The mitigated level of service at the Road A and Sutterville Road intersection is lower under the Single Intersection Alternative. Specifically, the intersection would continue to operate at substandard level at LOS D with 41.5 seconds of delay in the PM peak hour under cumulative conditions even after the recommended mitigation measures are implemented.
- The Single Intersection Alternative requires changes to the existing street network and right-of-way acquisition.

Split Intersection Alternative

The advantage of the Split Intersection Alternative is:

- The level of service at the Road A and Sutterville Road intersection is better than the Single Intersection Alternative. The intersection would operate at LOS C or better after the recommended mitigation measures are implemented.

The disadvantages of the Split Intersection Alternative are:

- As discussed under the Baseline Intersection Operation section, safety hazard may be created by vehicles traveling from Pacific Avenue to Road A or from Road A to Pacific Avenue. A no-right-turn-on-red restriction (RTOR) is needed at both intersections to resolve this potential safety issue. If the no RTOR restriction is applied, the level of service at the Road A intersection would degrade to substandard conditions. For instance, in the PM peak hour under cumulative conditions, the intersection operation would drop from LOS C with 28 seconds of delay to LOS D with 54.8 seconds of delay.
- Bicyclists who wish to cross Sutterville Road would also face the same difficult weaving maneuvers.
- The Split Intersection Alternative extends the eastbound left-turn pocket to west of Pacific Avenue in order to accommodate the heavy movement onto Road A. The necessary distance at Pacific Avenue between the two left-turn pocket segments may cause the signal to gap out early; thereby vehicles waiting in the western pocket segment might not be able to clear the eastern segment and would have to stop again. Any increase in gap time to remedy this situation would result increase delay at the intersection.
- Vehicles eager to make the eastbound left-turn may be caught in the Pacific Avenue intersection when the left-turn arrow turns red sooner than anticipated.

Recommendation

The Single Intersection Alternative is clearly the preferred design concept for reconfiguration of access to the South Sutterville Road area. The mitigated Single Intersection Alternative would operate at LOS C or better and avoid operational inefficiencies associated with the Split Intersection Alternative. The Single Intersection Alternative would also provide safer traffic operations and better service for pedestrians and bicyclists than the Split Intersection Alternative. The Single Intersection Alternative is more consistent with the City's goal

of providing a safe and efficient transportation system and a pedestrian-friendly environment.

Intersection Summary

~ Volume exceeds capacity, queue is theoretically infinite.
Queue shown is maximum after two cycles.

95th percentile volume exceeds capacity, queue may be longer.
Queue shown is maximum after two cycles.
