Executive Summary

This Water Quality Assessment Report (WQAR) provides information concerning federal, state, and local permitting requirements related to hydrology and water quality for the I Street Bridge Replacement Project (proposed project). The proposed project involves construction of a new bridge across the Sacramento River approximately 1,100 feet upstream of the existing I Street Bridge (Figures 1 and 2) and approximately 3,000 feet downstream of the American River. The existing bridge will remain in place, but the associated roadway approaches will be removed. In both Sacramento and West Sacramento, two alternatives for portions of the roadway design are being considered. In the City of Sacramento, two roadway design alternatives address the Railyards Boulevard/Jibboom Street/Bercut Drive intersection. In the City of West Sacramento, two residential access alternatives address properties cut off by the proposed C Street alignment.

The project is located on the Sacramento River within the northern portion of the Sacramento-San Joaquin River Delta in the Lower Sacramento Valley Watershed and the Sacramento Valley Groundwater Basin. The Sacramento River (Knights Landing to the Delta) is impaired for chlordane, DDT (dichlorodiphenyltrichloroethane), dieldrin, mercury, PCBs (polychlorinated biphenyls), and unknown toxicity.

Potential impacts of the proposed project on existing water quality conditions in the Sacramento River include temporary increases in sediments, oil, grease, and chemical pollutants during construction, as well as potential long-term discharges of sediments and other pollutants collected in storm water runoff. Short-term or temporary construction impacts on water quality have the potential to occur during land disturbance activities, material and equipment use and storage at staging areas, and in-water construction activities. Long-term impacts on water quality could occur from increased impervious area, roadway operations, and operation and maintenance activities such as bridge construction maintenance, inspections, and landscaping maintenance.

Impacts from these activities would be avoided or minimized because all construction activities within the Sacramento River would comply with a variety of permits and requirements from agencies, including the Central Valley Regional Water Quality Control Board, U.S. Army Corps of Engineers, California Department of Fish and Wildlife, and the Cities of Sacramento and West Sacramento.

In addition to agency coordination and permit compliance, the proposed project design includes drainage improvements, such as rock slope protection and improved storm drainage facilities. These measures will maintain pre-project drainage patterns (i.e., flows and rates) and minimize the potential for discharges of pollutants to the Sacramento River.

Chapter 1 Introduction

1.1 Project Description

The City of Sacramento, in cooperation with the City of West Sacramento and the California Department of Transportation (Caltrans), proposes to construct a new bridge over the Sacramento River to replace the vehicle crossing that is currently accommodated by the existing I Street Bridge in order to remove a series of functionally obsolete or structurally deficient bridges (i.e., approach structures). The new connection also would reduce future traffic congestion, improve operations and safety, serve multiple modes of transportation, and comply with current American Association of State Highway and Transportation Officials, Caltrans, and local agency design standards.

The project is subject to state and federal environmental review requirements because of use of federal Highway Bridge Program (HBP) funds from the Federal Highway Administration (FHWA). Accordingly, project documentation is being prepared in compliance with both the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA). The City of Sacramento is the lead agency under CEQA, with the City of West Sacramento as a responsible agency, and Caltrans is the lead agency under NEPA. The FHWA's other responsibilities for environmental review, consultation, and any other action required in accordance with applicable federal laws for this project will be carried out by Caltrans under its assumption of responsibility pursuant to 23 United States Code (USC) 327.

This project is included in the Sacramento Area Council of Governments (SACOG) *Metropolitan Transportation Plan/Sustainable Communities Strategy 2035* (MTP/SCS).

1.1.1 Project Location

The proposed project is located over the Sacramento River between the Cities of Sacramento and West Sacramento, approximately 1,000 feet north of the existing I Street Bridge (Figure 1). The project limits starting within the City of Sacramento consist of Railyards Boulevard from 200 feet east of Bercut Drive on the east, continuing west over the Sacramento River into the City of West Sacramento along C Street, and terminating approximately 100 feet west of the 5th Street intersection. The project limits also extend along Bercut Drive approximately 500 feet north of Railyards Boulevard, along Jibboom Street 550 feet north of Railyards Boulevard and 300 feet south of Railyards Boulevard, along 3rd Street 50 feet north and south of C Street, along 4th Street 50 feet north and south of C Street, and along 5th Street 50 feet north and south of

C Street. The total length of the project is approximately 0.42 mile along C Street and Railyards Boulevard.

1.1.2 Purpose and Need

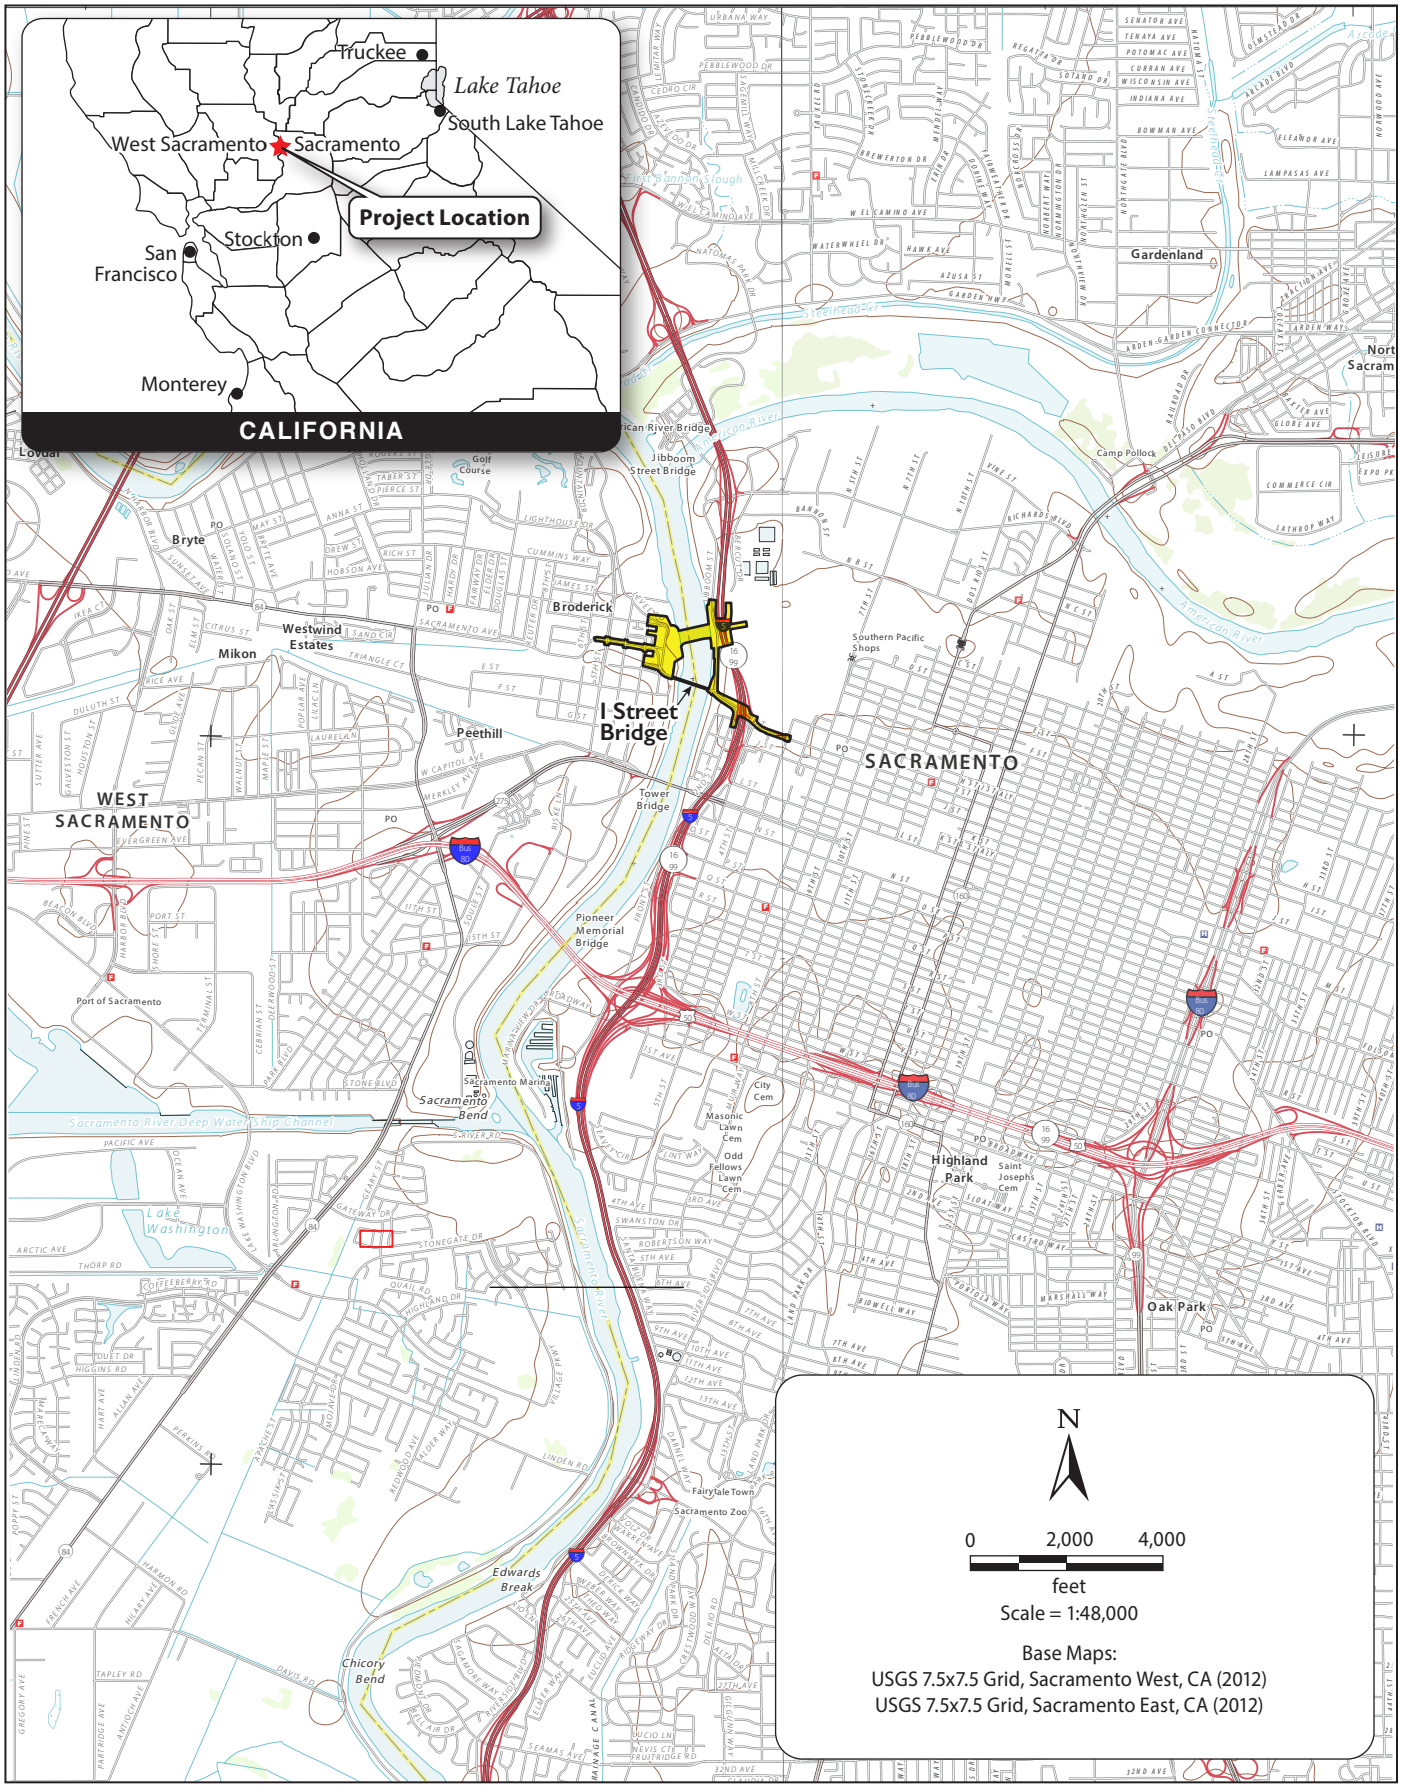
The proposed project would construct a new bridge over the Sacramento River between the Cities of Sacramento and West Sacramento to replace the vehicle crossing that is currently provided by the existing I Street Bridge. Construction of the proposed project has independent utility; the project is not dependent on other projects or improvements to meet the purpose and need.

Termini for the proposed project were developed through an iterative process involving engineering design and traffic operations analysis. Preliminary design concepts were tested with the traffic operations analysis model to evaluate how lane configurations influenced peak-hour conditions.

1.1.2.1 Purpose

The purpose and objectives of the project are listed below.

- The project should construct a new public crossing of the Sacramento River north of the Union Pacific Railroad-owned I Street Bridge from C Street in the City of West Sacramento to Railyards Boulevard in the City of Sacramento, consistent with the adopted findings of the Sacramento River Crossings Alternatives Study for Bridge Location 2 in the North Market Area.
- The new bridge should meet the requirements of the Neighborhood Friendly Bridge definition that the City of Sacramento City Council adopted by resolution on October 18, 2011, which is defined by the following elements.
  - A facility whose primary function is local connectivity rather than regional travel and primarily serves short local trips.
  - A bridge which serves all users, including motorists, bicyclists, pedestrians, low-energy vehicles, and public transit riders.
  - A bridge with aesthetics and dimensions which are architecturally pleasing and contextually appropriate for the adjacent neighborhoods.
  - A bridge that does not exceed or expand the already-planned capacity of the approach roadways (i.e., no widening of approaches just to accommodate bridge flows).



Graphics ... 00203.14 (6/10/15) AB

Figure 1
Vicinity Map

  - A facility which is designed with a target speed equal to or less than the approach roadways.
  - A bridge which reduces the growth in vehicle miles traveled in the adjacent communities.
  - A bridge that does not connect directly to streets which are primarily residential in character.
  - A bridge that is consistent with the Need and Purpose statement [the adopted Sacramento River Crossings Alternatives Study statement] as articulated.

- In addition to the Neighborhood Friendly Bridge definition, the project should include pedestrian and bicycle facilities in the new public crossing that meet Americans with Disabilities Act (ADA) requirements, and facilitate connections to and from the new crossing and the Sacramento River Parkway and Riverfront Park trails.
- The proposed project also would need to construct a movable bridge that satisfies the vertical clearance and river navigation requirements of the U.S. Coast Guard (USCG).
- The project design should not preclude future addition of a streetcar, a separate, stand-alone project being developed by the Cities of West Sacramento and Sacramento.
- The new bridge also is intended to improve the connectivity to, and accessibility of, businesses, recreational areas, and new or redevelopment opportunity sites located in the urban core of Sacramento and West Sacramento.

1.1.2.2 Need

The project is needed for the following reasons.

- The existing I Street Bridge does not fully comply with current design and traffic operation standards due to the following conditions.
  - I Street Bridge limits or restricts traffic capacity and multimodal use. The current bridge width is not sufficient to provide adequate traffic operations, bicycle lanes, or the ability for transit service across the bridge.
  - The I Street Bridge and the four associated approach structures are on the federal eligible bridge list for federal funds for replacement and/or rehabilitation through the HBP. The I Street Bridge has been classified as functionally obsolete, and the existing approach structures have been classified as structurally deficient. The Cities of Sacramento and West Sacramento have decided to pursue replacement through the HBP.

- As adopted by the Sacramento City Council, new crossings of the Sacramento River between the City of Sacramento and City of West Sacramento shall be Neighborhood Friendly. In coordination with staff from the City of West Sacramento and SACOG, the definition for a Neighborhood Friendly Bridge was developed by the City of Sacramento, and the Sacramento City Council adopted the definition by resolution in October 2011. The replacement bridge structure is required to be consistent with the Neighborhood Friendly Bridge definition.
- In addition to the Neighborhood Friendly Bridge requirements, lack of ADA compliance, non-standard and non-continuous sidewalks, and lack of bicycle facilities discourage walking and bicycling on the existing I Street Bridge.
- Section 9 of the Rivers and Harbors Act requires any local, state, or federal agency planning to construct a bridge over a navigable waterway to apply for a bridge permit through the USCG. The USCG requires the new bridge to meet or exceed the existing vertical clearance along the river, which is currently set by the U.S. 50 Pioneer Bridge. In order to comply with the Neighborhood Friendly Bridge definition and meet the USCG requirements for navigation clearance, the new bridge will need to be movable.
- The MTP/SCS identifies that a proposed streetcar will cross over the new bridge from Sacramento to West Sacramento. While the streetcar will be a separate, stand-alone project, the bridge design must not preclude the future addition of a streetcar.
- Limited connectivity to the riverfront reduces the potential to achieve planned urban development and redevelopment of opportunity sites identified in the adopted plans of Sacramento and West Sacramento.

1.1.3 Project Alternatives

This section describes the proposed action and the design alternatives that were developed to meet the identified need through accomplishing the defined purpose(s), while avoiding or minimizing environmental impacts. The alternatives under consideration are one bridge alignment for the new bridge over the Sacramento River and two alternatives for portions of the roadway design in Sacramento and in West Sacramento.

- City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection
  - Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive
  - Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

- City of West Sacramento Residential Access
  - Alternative 1—C Street Connection to B Street
  - Alternative 2—C Street Connection to 3rd Street
- No-Build (No-Project) Alternative

The proposed project is located in Sacramento and Yolo Counties, over the Sacramento River and between the Cities of Sacramento and West Sacramento, and approximately 1,000 feet north of the existing I Street Bridge (Figure 1). The total length of the project is approximately 0.42 mile along C Street and Railyards Boulevard. The purpose of the project is to construct a new public crossing of the Sacramento River north of the Union Pacific Railroad-owned I Street Bridge from C Street in the City of West Sacramento to Railyards Boulevard in the City of Sacramento in order to remove a series of functionally obsolete or structurally deficient bridges, consistent with the adopted findings of the Sacramento River Crossings Alternatives Study for Bridge Location 2 in the North Market Area.

1.1.3.1 Build Alternatives

One alignment is proposed for the new bridge over the Sacramento River. A new approximately 860-foot bridge, consisting of two vehicle lanes, on-street Class II bike lanes, and sidewalks along both sides, is proposed. The bridge would include two fixed-span approach structures, approximately 200 feet and 270 feet in length, that tie into the Sacramento and West Sacramento banks of the river, respectively. The center span of the bridge would be an approximately 330-foot movable span that meets the USCG requirements. Roadway improvements on Railyards Boulevard in Sacramento and C Street in West Sacramento also are proposed. In both Sacramento and West Sacramento, two alternatives for portions of the roadway design are being considered. Figure 2 depicts the proposed project and the roadway design alternatives, described below.

- City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection
  - Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive
  - Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

In the City of Sacramento, Alternative 1 consists of a signalized intersection at Jibboom Street and Bercut Drive, while Alternative 2 consists of a roundabout between these two intersections. Beyond the Jibboom Street and Bercut Drive intersections, the remaining project elements and limits in the City of Sacramento are similar under both alternatives.

- City of West Sacramento Residential Access
  - Alternative 1—C Street Connection to B Street
  - Alternative 2—C Street Connection to 3rd Street

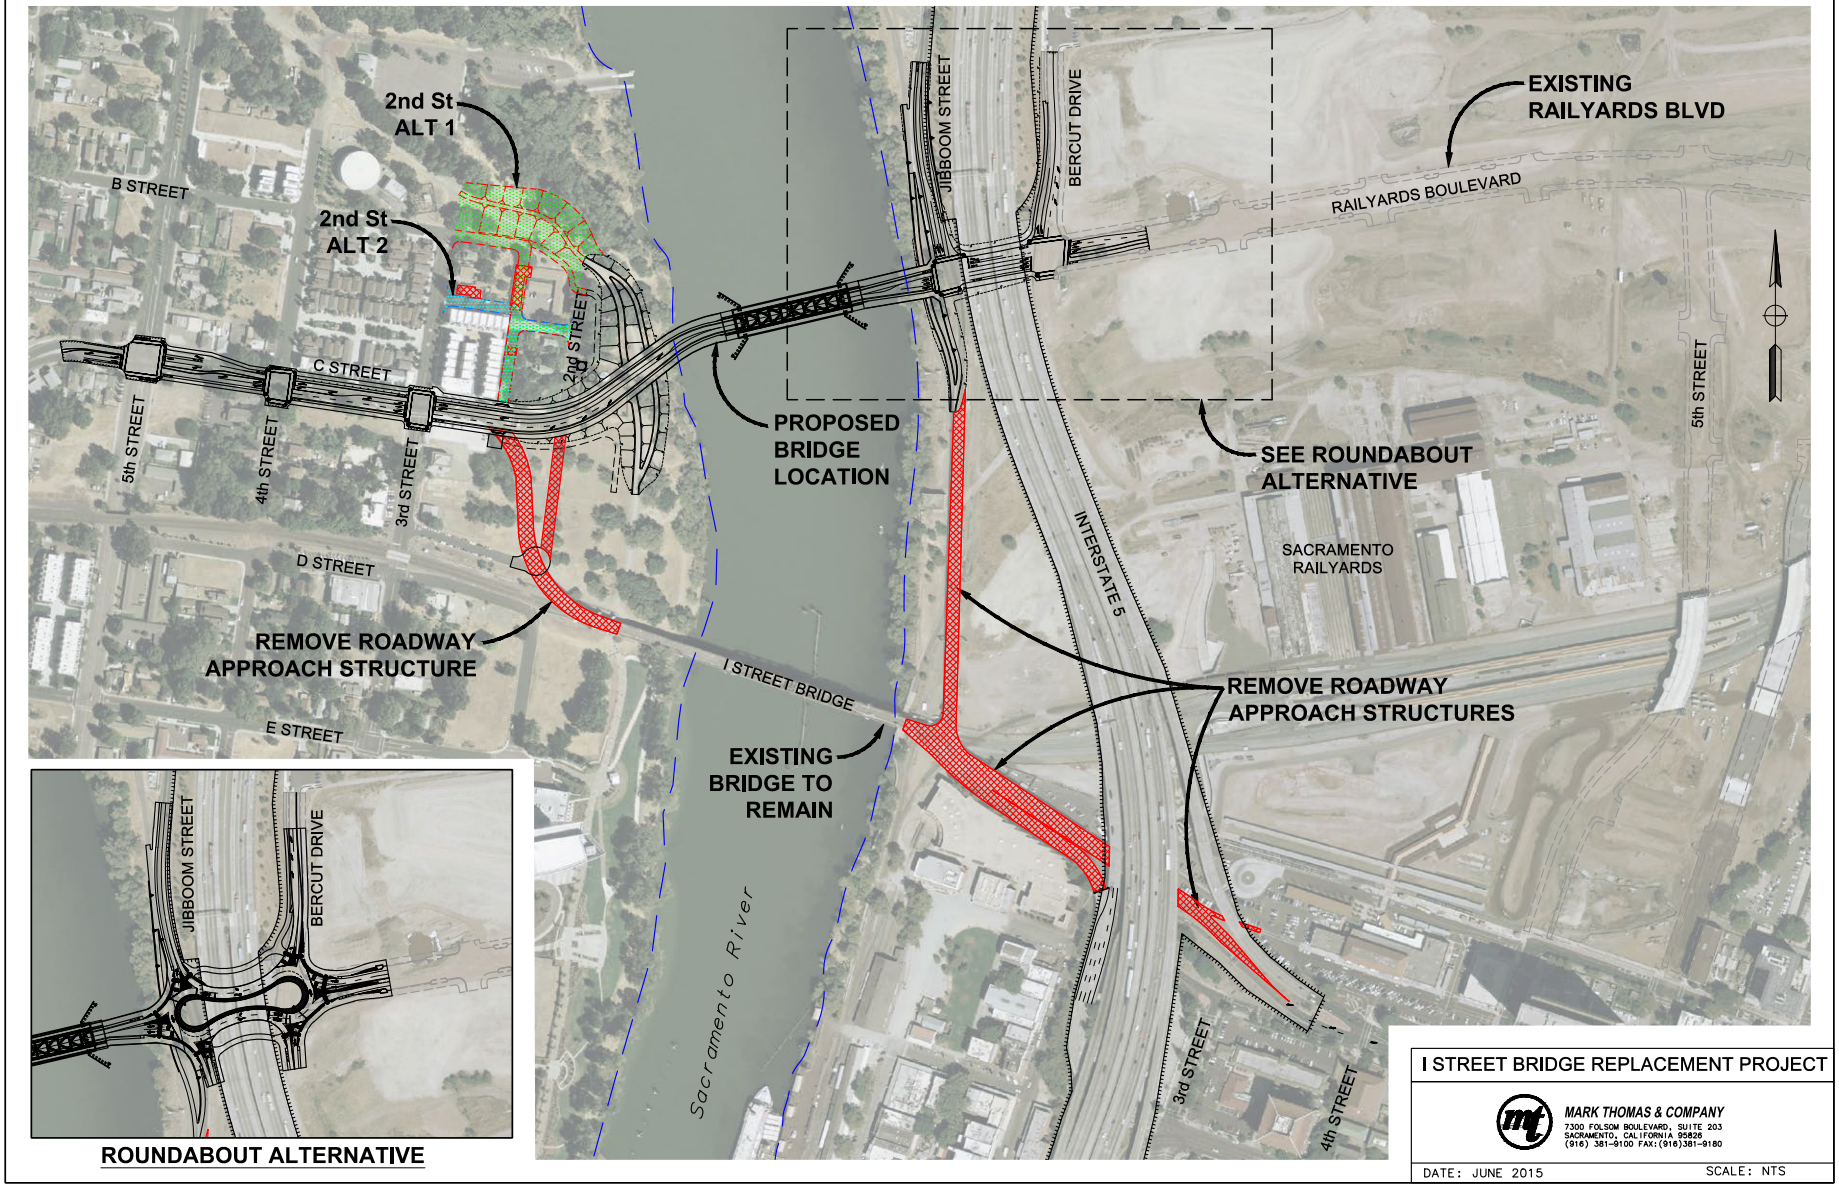
In the City of West Sacramento, the proposed C Street alignment would cut off access to four residential parcels and one multifamily parcel located along 2nd Street, north of C Street. Two alternatives are proposed for maintaining access to these parcels. Alternative 1 would construct a new connection to C Street, approximately 150 feet east of the C Street/3rd Street intersection, that would extend north to B Street and then ultimately connect to the 3rd Street/B Street intersection. Alternative 2 would connect to the same location at C Street as Alternative 1, approximately 150 feet east of the C Street/3rd Street intersection, but would continue north approximately 300 feet, then make a 90-degree left turn, and connect to 3rd Street approximately 300 feet north of C Street.

Common Design Features of the Build Alternatives

The proposed project would construct a new bridge over the Sacramento River between Sacramento and West Sacramento to replace the vehicular crossing that is provided by the existing I Street Bridge. The project would facilitate vehicular and multimodal traffic over the river in order to reduce traffic congestion, improve safety, and remove a number of structurally deficient or functionally obsolete bridges that have reached the limit of their design life. While the existing I Street Bridge over the Sacramento River would remain in-place, the approach structures leading up to the bridge from both directions would be demolished. See Figure 2 for a depiction of the project limits and the approach structures that would be removed.

The Sacramento River is considered to be a navigable waterway of the United States. Under the provisions of the General Bridge Act of 1946, as amended, the USCG must approve proposed location and plans for bridges over navigable waters of the United States prior to commencing construction. In order to comply with the adopted Neighborhood Friendly Bridge definition and the USCG requirement to maintain navigation along the river, the new bridge is proposed to be a movable bridge.

Common design features of the build alternatives are listed below.



Graphics ... 00203.14 (6/18/15) AB

Figure 2
Proposed Project

New Bridge Construction and Roadway Modifications

Bridge Construction

The proposed project would construct a new bridge over the Sacramento River. The total bridge length would be approximately 860 feet long, consisting of two vehicle lanes, on-street Class II bike lanes, and sidewalks along both sides of the bridge. The bridge would include two fixed-span approach structures that tie into the Sacramento and West Sacramento banks of the river and are approximately 200 feet and 270 feet in length, respectively. The center span of the bridge would be a movable span that meets the USCG requirements. The movable span is anticipated to be approximately 330 feet in length. The bridge soffit elevation would be set 3 feet above the 200-year water surface elevation to comply with the Central Valley Flood Protection Board (CVFPB) freeboard requirements.

The two fixed-span approach structures would be 72 feet wide, with a superstructure depth (or total bridge thickness) of approximately 6 feet. Each approach structure would be a two-span bridge. The abutment at one end of the structure would be constructed on the banks of the river, a center pier would be placed within the river approximately around the existing bank toe of slope, and the other end of the approach structure would be constructed on the piers for the movable span.

Based on coordination with the USCG, the movable span would provide a 278-foot clear channel opening approximately centered at the middle of the river. As such, the movable span has been identified as a vertical lift bridge, which would raise the bridge to a minimum vertical clearance of 59 feet over the maximum river elevation of 31 feet (measured to the NGVD 29 vertical datum). The truss depth of the movable span would be approximately 40 feet, with 6 feet of the structure being below the bridge deck and 34 feet above the bridge deck. The vertical towers would be approximately 130 feet tall, measured from the bridge soffit elevation. The vertical towers would be approximately 33 feet in thickness and the same width as the bridge deck. The total bridge width on the movable span would be 81 feet.

Due to the existing soil conditions, the bridge would be constructed on deep pile foundations. The abutments for the fixed-span approach structures at the river bank would consist of approximately 50 piles per abutment that are driven or cast-in-drill-hole (CIDH), to a depth of approximately 70 feet below the original ground elevation. The center piers for the two fixed-span approach structures (located approximately at the bank toe of slope in the river, below the ordinary high water mark) would consist of 50 driven or CIDH piles per pier that are approximately 70 feet below the original ground elevation. If driven piles are selected for either the abutments or piers, the piles would be precast concrete or steel. The foundations for the

movable span would consist of four large-diameter cast-in-steel-shell piles per pier. Each pile would be 9 feet in diameter, extending approximately 140 feet below the original ground elevation.

Erosion control measures would be installed around the proposed bridge foundations to prevent future scour at the bridge supports. It is anticipated that rock slope protection (RSP) would be installed around the bridge abutments and piers within the water to control erosion.

A bridge fender system also is planned around the movable span piers to protect the piers from errant watercrafts that are navigating along the river. The fender system would include approximately 30 driven concrete or wooden piles around each of the movable span piers. The piles would be driven to a depth of approximately 30 feet below the original ground elevation.

Temporary Falsework

Temporary falsework platforms (trestles) would be required to construct the proposed bridge foundations and approach structures. The platforms would be constructed during the first construction season using temporary piles within the river. Each temporary platform would include approximately 80 driven steel piles; the piles would be either 16-inch diameter or 16-inch H piles. Once installed, the temporary trestle piles would remain in the river throughout the duration of construction and would be removed in the second construction season following completion of construction. In addition, temporary cofferdams would be required to construct the bridge piers within the water. The cofferdams would consist of temporary sheet piles installed around the individual piers. The sheet piles would be installed and removed with a vibratory hammer. Dewatering inside the cofferdams would be required.

Roadway Modifications

City of Sacramento

In Sacramento, Bercut Drive would be modified from Railyards Boulevard north approximately 500 feet. Bercut Drive would be designed to have two northbound lanes at the Railyards Boulevard intersection, tapering down to one northbound lane at the northern project limits, and one southbound lane. Improvements to Bercut Drive south of Railyards Boulevard are not part of, nor needed for, the proposed project and would be constructed if needed as part of a separate future project.

Proposed improvements on Jibboom Street would extend 550 feet north of Railyards Boulevard. The roadway would consist of one travel lane in each direction, on-street Class II bike lanes, sidewalk along the west side of the roadway, and retaining walls of various heights along both

sides of the road. Extension of Jibboom Street south of Railyards Boulevard is not included with, nor needed for, the proposed project and would be constructed if needed as part of a separate future project.

The proposed roadway profile for Railyards Boulevard would be approximately 6 feet higher than the original ground elevation at the Jibboom Street intersection. The profile adjustment is needed in order to satisfy the CVFPB requirements to provide 3 feet of clearance between the 200-year-flood water surface elevation and the bridge soffit (or low chord of the bridge).

City of West Sacramento

Between the bridge touchdown location along C Street in West Sacramento and the 4th Street/ C Street intersection, the roadway would consist of one westbound travel lane, two eastbound travel lanes (the two eastbound travel lanes would taper down to one eastbound lane east of the 3rd Street intersection), a center left-turn lane, on-street Class II bike lanes, on-street parking along the north side of the roadway, and sidewalks along both sides of the roadway. As the roadway through this section currently consists of the proposed number of travel lanes, the widening through this area is primarily needed to support the Class II bike lanes and wider sidewalks.

Along C Street between 4th Street and 5th Street, the roadway would consist of one travel lane in each direction, left-turn lanes, on-street Class II bike lanes, and sidewalks along both sides of the road. All of the improvements through this section would be accommodated within the existing roadway limits.

Class I Bikeway and Levee Modifications and Improvements

City of Sacramento

The existing Class I Sacramento River Parkway along Jibboom Street would be reconstructed approximately 500 feet north and 300 feet south of Railyards Boulevard as part of the proposed project. In order to maintain a continuous off-street Class I path along this section, the path would be grade-separated under the proposed bridge structure. Cyclists and pedestrians approaching Railyards Boulevard in either direction would have the option to continue along the path under the new structure, avoiding the need to cross the roadway. Cyclists and pedestrians who are traveling along the path also would have the option to connect to Railyards Boulevard and cross over the proposed bridge into West Sacramento or turn east into Sacramento. Due to the limited horizontal clearance between the river and the Interstate 5 (I-5) viaduct structure, retaining walls would be needed along the path to account for the vertical elevation difference

between Jibboom Street and the path that continues under the proposed bridge structure. The maximum retaining wall height along the bike path would be 16 feet.

City of West Sacramento

The proposed project would require improvements to the existing levee along the West Sacramento side of the river, where the proposed bridge alignment would connect to C Street. The existing levee does not meet current standards required by Title 23 of the California Code of Regulations (CCRs). Extending approximately 300 feet north and south of the proposed C Street alignment, the levee cross-section would be reconstructed to meet current design standards, which would require 3:1 side slopes on the landside and waterside of the levee, and a 20-foot-wide crown at the top of the levee. The levee improvements also would include a slurry cutoff wall extending to a depth of 110 feet below the original ground elevation. In addition, the proposed roadway profile would be approximately 6 feet higher than the original ground elevation as it crosses over the levee. In order to maintain access to the levee for inspection and maintenance services, access roads would be constructed from the new roadway to the top of the improved levee section. The proposed grading for the levee would require relocation of the existing water tower that is located along 2nd Street, just north of the proposed C Street alignment. The tower would be relocated to the northwest, approximately 43 feet from its existing location.

The new levee maintenance road also would serve as the future Class I River Walk Park trail extension in West Sacramento. Similar to the trail improvements proposed as part of the project in Sacramento, the trail would be grade-separated under the proposed bridge structure. Cyclists and pedestrians approaching C Street in either direction would have the option to continue along the trail under the new structure, avoiding the need to cross the roadway. Cyclists and pedestrians who are traveling along the trail also would have the option to connect to C Street to cross over the proposed bridge into Sacramento or head west on C Street.

Storm Water Drainage Management

Drainage for the proposed roadway would be conveyed to the existing storm drain system installed within Railyards Boulevard and C Street. Railyards Boulevard currently drains storm water to the east along the roadway and then into a retention basin south of Railyards Boulevard. C Street drains storm water west along the roadway and then ultimately south beyond the project limits.

As is standard with all construction projects, the contractor would be required to install temporary best management practices (BMPs) to control any runoff or erosion from the project

site into the surrounding waterways. These temporary BMPs would be installed prior to any construction operations and would be in place for the duration of the contract. The removal of these BMPs would be the final operation, along with project site cleanup.

Structure Demolition and Roadway Modifications

Following completion of the new bridge connections at Railyards Boulevard and C Street, traffic would be diverted to the new bridge, and the four existing approach structures to the I Street Bridge would be removed. Bridge numbers 24C0364L, 24C0364R, 22-0033, and 22C0154 would be demolished and the foundations would be removed to a depth of 3 feet below the original ground elevation. Encroachment permits from Caltrans and Union Pacific Railroad would be needed to complete the bridge removal. The existing I Street Bridge is owned and operated by Union Pacific Railroad and would continue to remain in-place and used by trains following construction of the new bridge.

As part of the removal of the existing approach structures, the project would include modifications to I Street within the City of Sacramento from the southbound I-5 on-ramp east to the 5th Street intersection. The modification would include signing and striping revisions, demolition of existing roadway sections that are no longer required, and removal of bridge abutments and foundations.

Staging, Storage, and Proposed Access during Construction

Two staging areas would be used to store materials and equipment during construction, such as pipe materials, precast manholes and drop inlets, steel girders, piles, and rebar, along with the construction equipment when not in use. One area would be located south of Railyards Boulevard under I-5 in Sacramento; the other area would be located west of the landward side of the levee, south of the new bridge location in West Sacramento. The staging area located along Railyards Boulevard would be accessed via the existing intersection at Jibboom Street. The staging area in West Sacramento would be accessed via the existing 2nd Street connection at 3rd Street, south of C Street. The staging areas would be in use throughout the construction duration; the areas would be returned to their pre-project conditions at the completion of the project.

Utility Relocations

A number of public and private utilities would need to be relocated or adjusted to grade as part of the project, including existing water, sewer, gas, electric, and communication facilities within Jibboom Street, Bercut Drive, C Street, and 2nd Street.

Traffic Management and Detours during Construction

While most of the project would be constructed outside of existing roadways, some areas would require temporary detours or staged construction.

Along Jibboom Street at the proposed Railyards Boulevard intersection, the new roadway profile would be raised approximately 6 feet above the original ground elevation. To maintain access to the existing Jibboom Street viaduct south of Railyards Boulevard during the roadway construction, a temporary access road would be needed. The proposed temporary access road would connect to the existing Jibboom Street viaduct abutment approximately 350 feet south of Railyards Boulevard. The temporary road would then continue under I-5 and connect to the Railyards Boulevard/Bercut Drive intersection. The temporary road would require placement of temporary fill material and a roadway structural section that would be removed after construction of the new bridge. Traffic traveling north along Jibboom Street would continue north along Bercut Drive to access the Richards Boulevard/I-5 interchange.

In order to complete the improvements at Jibboom Street and Railyards Boulevard, Jibboom Street would be closed to traffic approximately 600 feet north of Railyards Boulevard. Traffic traveling south along Jibboom Street to continue over the existing I Street Bridge into West Sacramento would be detoured over to Bercut Drive at Richards Boulevard. Traffic would then use the temporary access road to connect to the Jibboom Street viaduct structure. The temporary access road would be in place for approximately 2 years, after which traffic would use the new roadways and new bridge.

The Sacramento River Parkway trail along Jibboom Street also would require temporary re-routing during construction. The temporary alignment for the trail would follow the temporary Jibboom Street alignment south of Railyards Boulevard. Cyclists and pedestrians would then continue following a detour north along Bercut Drive to Richards Boulevard, where they could then connect back to the Parkway on the west side of I-5. The detour would be in place for approximately 2 years.

During construction, traffic along C Street would be maintained along the existing approach structure until the new bridge is constructed.

Project Construction Sequence

New bridge and roadway construction would occur first, followed by demolition of the four approach structures that connect to the existing I Street Bridge. Once the new bridge and roadways are constructed, traffic would be diverted to the new bridge in order to allow

demolition adjacent to the existing bridge. Construction of the project is expected to take approximately 30 months.

Property Acquisition

The project would require temporary and permanent property acquisitions along C Street, 3rd Street, and 2nd Street within the City of West Sacramento and along Railyards Boulevard, Jibboom Street, Bercut Drive, and I Street within the City of Sacramento.

Along C Street, temporary and permanent acquisitions would be required along the south side of the roadway to accommodate the construction of standard shoulders, bike lanes, and sidewalks—from the intersection of 4th Street to the Sacramento River.

Along 3rd Street and 2nd Street, temporary and permanent acquisitions would be needed from the Union Pacific Railroad on the south, to just north of the B Street intersections, for construction of the proposed roadway and levee improvements.

Along Railyards Boulevard, Jibboom Street, and Bercut Drive, temporary and permanent acquisition would be needed from the current state-owned right-of-way for I-5, for construction of the roadway. In addition, temporary and permanent acquisitions would be needed along Jibboom Street for the proposed temporary detour road and Class I bikeway improvements.

Temporary acquisition would be required along the existing I Street connection to facilitate removal of the existing viaduct structures. Due to the limited space available in Old Sacramento, it is anticipated that construction activities would occur from the parking lot at the intermodal station.

Unique Features of Build Alternatives

In both the City of Sacramento and the City of West Sacramento, two alternatives for portions of the roadway design are being considered.

City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection

Alternative 1 consists of a signalized intersection at Jibboom Street and Bercut Drive, while Alternative 2 consists of a roundabout between these two intersections. Beyond the Jibboom Street and Bercut Drive intersections, the remaining project elements and limits are similar under both alternatives.

Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive

Under Alternative 1, Railyards Boulevard would be extended west over the Sacramento River; east of Bercut Drive. Railyards Boulevard would consist of two westbound lanes and one eastbound lane. Between Jibboom Street and Bercut Drive, Railyards Boulevard would consist of two westbound lanes and three eastbound lanes; two eastbound lanes would be trapped into left-turn lanes onto Bercut Drive, and one eastbound lane would continue along Railyards Boulevard. West of the Jibboom Street intersection, Railyards Boulevard would consist of one lane in each direction.

Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

Under Alternative 2, Railyards Boulevard would be extended west over the Sacramento River. East of Bercut Drive, Railyards Boulevard would consist of two westbound lanes and one eastbound lane. Between Jibboom Street and Bercut Drive, Railyards Boulevard would consist of a roundabout with two lanes in each direction. One westbound lane would be a trap onto northbound Jibboom Street, and one westbound lane would continue onto the new bridge. One eastbound lane would be trapped into left-turn lanes onto Bercut Drive, and one eastbound lane would continue along Railyards Boulevard. West of Jibboom Street, Railyards Boulevard would consist of one lane in each direction.

City of West Sacramento Residential Access

The new C Street alignment would cut off access to four residential parcels and one multifamily parcel located along 2nd Street, north of C Street. Two alternatives are proposed for maintaining access to these parcels.

Alternative 1—C Street Connection to B Street

Alternative 1 would construct a new connection to C Street approximately 150 feet east of the 3rd Street intersection. The new access road would be 30 feet wide, extend north to B Street, and then ultimately connect to the 3rd Street/B Street intersection. This alternative would require right-of-way acquisitions from six individual parcels and removal of two structures. One structure is located on APN 010-101-010 and appears to be an individual residence. Another structure is located on APN 010-101-013 and appears to be an apartment building that supports up to four individual apartments. As B Street currently is constructed along the existing levee, the roadway improvements also would require an additional 500 feet of improvements to the levee. Similar to the improvements identified along C Street, the levee cross-section would be reconstructed to meet current design standards, which require 3:1 side slopes on the landside and waterside of the levee, with a 20-foot-wide crown at the top of the levee. The levee

improvements also would include a slurry cutoff wall that extends to a depth of 110 feet below the original ground elevation.

Alternative 2—C Street Connection to 3rd Street

Alternative 2 would connect to the same location at C Street, approximately 150 feet east of the 3rd Street intersection and continue north approximately 300 feet. This alternative would then make a 90-degree left turn and connect to 3rd Street approximately 300 feet north of C Street. This alternative would require right-of-way acquisition from seven individual parcels and removal of three structures. One structure is located on APN 010-101-010 and appears to be an individual residence. Another structure is located on APN 010-101-013 and appears to be an apartment building that supports up to one individual apartment. The last structure is located on APN 010-101-004 and appears to be an individual residence.

1.1.3.2 No Build (No-Project) Alternative

Under the No Build Alternative, the existing I Street Bridge would remain in use for vehicle, bicycle, and pedestrian access between the Cities of Sacramento and West Sacramento. No changes to traffic patterns on I Street or C Street would occur. The four approach structures would remain in place and in use; and there would be no changes to existing roadways, levees or Class I bikeways.

Improvements and development of transportation infrastructure would continue following the General Plans of both cities, the Sacramento Railyards Specific Plan (approved December 2007), and the Washington Specific Plan (adopted May 1996). The Sacramento Railyards Specific Plan identifies the extension of Railyards Boulevard west to a Tee intersection at Jibboom Street. Railyards Boulevard at Bercut Drive would consist of two westbound lanes and one eastbound lane. The same number of lanes on Railyards Boulevard would extend west to the intersection with Jibboom Street; at this point, the left westbound lane on Railyards Boulevard would become a dedicated left-turn onto southbound Jibboom Street, and the right westbound lane would be a dedicated right-turn onto northbound Jibboom Street.

In West Sacramento, future changes to C Street would be based on the Washington Specific Plan, which identifies 12-foot-wide sidewalks and 7-foot-wide Class II bike lanes along the roadway. The connection to the I Street Bridge would not change.

1.1.3.3 Permits and Approvals Needed

The following permits and coordination likely will be required for the project (Table 3).

Table 1. Permits and Approvals Needed

Agency	Permit/Approval	Status
U.S. Coast Guard	Authorization under General Bridge Act of 1946, as amended, for new bridge over navigable waters of the United States	Initiated
U.S. Army Corps of Engineers	Section 404 Clean Water Act authorization for fill of waters of the United States	Not yet initiated
National Marine Fisheries Service	Coordination regarding threatened and endangered species	Not yet initiated
U.S. Fish and Wildlife Service	Coordination regarding threatened and endangered species	Not yet initiated
California Department of Fish and Wildlife	Section 1602 Department of Fish and Game Code Streambed Alteration Agreement	Not yet initiated
Central Valley Regional Water Quality Control Board	Section 401 Water Quality Certification and coverage under the existing Caltrans National Pollutant Discharge Elimination System (NPDES) Permit (Order No. 00-06-DWQ)	Not yet initiated
State Water Resources Control Board	NPDES Permit for Stormwater Discharges Associated with Construction Activities	Not yet initiated
Central Valley Flood Protection Board	Encroachment Permit	Not yet initiated
State Lands Commission	Lease of State Lands	Not yet initiated
Sacramento Area Flood Control Agency	Approval of changes to levee	Not yet initiated
West Sacramento Area Flood Control Agency	Approval of changes to levee	Not yet initiated
Sacramento Metropolitan Air Quality Management District	Formal notification prior to construction	Not yet initiated
Yolo-Solano Air Quality Management District	Formal notification prior to construction	Not yet initiated

1.2 Approach to Water Quality Assessment

This WQAR is intended to fulfill the requirements of NEPA and CEQA, and to provide information, to the extent possible, for National Pollution Discharge Elimination System (NPDES) permitting. The document includes a discussion of the proposed project, the physical setting of the project area, and the regulatory framework with respect to water quality. It also provides data on surface water and groundwater resources within the project area and the water quality of these waters, describes water quality impairments and beneficial uses, identifies potential water quality impacts/benefits associated with the proposed project, and recommends avoidance and/or minimization measures for potentially adverse impacts.

The WQAR is organized as follows.

- Chapter 1: Introduction
- Chapter 2: Regulatory Setting

- Chapter 3: Affected Environment
- Chapter 4: Environmental Consequences
- Chapter 5: Avoidance and Minimization Measures
- Chapter 6: References
- Chapter 7: Preparers Qualifications

Chapter 2 Regulatory Setting

This chapter defines the regulatory environment associated with water quality at the federal, state, and local levels. In particular, the chapter defines Caltrans' regulatory environment related to water quality.

Several permits must be approved prior to the project construction phase. Of the permits and approvals for the project shown in Table 1, the primary water quality permits that likely will be required for project construction include the Section 404 Clean Water Act (CWA) authorization for fill of waters of the United States (Section 404 Permit), Section 1602 Department of Fish and Game Code Streambed Alteration Agreement (Streambed Alteration Agreement), Section 401 Water Quality Certification (401 Certification), the NPDES Permit for Stormwater Discharges Associated with Construction Activities (Construction General Permit [CGP]), Low-Threat Dewatering Permit and General Dewatering Permit for Land Discharges.

2.1 Federal Laws and Requirements

2.1.1 Clean Water Act

The primary federal law regulating water quality is the CWA. In 1972 Congress amended the Federal Water Pollution Control Act, making the addition of pollutants to waters of the United States from any point source unlawful unless the discharge is in compliance with an NPDES permit. The objective of the CWA is "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters." EPA has delegated enforcement of the CWA in California to the State Water Resources Control Board (State Water Board) and its nine Regional Water Quality Control Boards (Regional Water Boards). The following CWA sections pertain to the project.

2.1.1.1 Sections 303, 304, and 305 – Impaired Waters, TMDLs, and Water Quality Criteria

The State of California adopts water quality standards to protect beneficial uses of state waters as required by Section 303(d) of the CWA and the Porter Cologne Water Quality Control Act (Porter-Cologne Act). Section 303(d) of the CWA established the total maximum daily load (TMDL) process to guide the application of state water quality standards (see the discussion of state water quality standards below). To identify candidate water bodies for TMDL analysis, the State Water Board generated a list of water quality–limited segments. These stream or river

segments are impaired by the presence of pollutants such as sediment and are more sensitive to disturbance because of this impairment.

Section 304(a)(1) of the CWA requires development of criteria for water quality that accurately reflect the latest scientific knowledge. These criteria are based solely on data and scientific judgments on pollutant concentrations and environmental or human health effects. Section 304(a) also provides guidance to states and tribes in adopting water quality standards. Criteria are developed for the protection of aquatic life as well as for human health.

In addition to the impaired water body list required by Section 303(d), Section 305(b) requires states to develop a report assessing statewide surface water quality. Both CWA requirements are addressed through development of a 303(d)/305(b) Integrated Report, which addresses both an update to the 303(d) list and a 305(b) assessment of statewide water quality. The State Water Board developed a statewide 2010 California Integrated Report (State Water Resources Control Board 2011) based on the Integrated Reports from each of the nine geographically separated Regional Water Boards. The 2010 California Integrated Report was approved by the State Water Board at a public hearing on August 4, 2010; and EPA issued its final decision and approval of the report on October 11, 2011.

All of the 303(d)-listed impaired waters with potential to be affected by the project are shown in Table 5 (see Section 3.3.4, List of Impaired Waters). These waters will be evaluated as part of the project, and minimization measures will be implemented to protect waters from further impairment.

2.1.1.2 Section 401 – Water Quality Certification

Under Section 401 of the CWA, any project requiring a federal license or permit that may result in a discharge to a water of the United States must obtain a 401 Certification, which certifies that the project will be in compliance with state water quality standards. The most common federal permit triggering 401 Certification is a CWA Section 404 permit, issued by the U.S. Army Corps of Engineers (USACE). The 401 Certifications are obtained from the appropriate Regional Water Board, dependent on the project location, and are required before USACE issues a Section 404 Permit.

In some cases, the Regional Water Board may have specific concerns with discharges associated with a project. As a result, the Regional Water Board may issue a set of requirements known as Waste Discharge Requirements (WDRs) under the State Water Code (Porter-Cologne Act). WDRs define activities, such as inclusion of specific features, effluent limitations, monitoring,

and plan submittals, that are to be implemented for protecting or benefiting water quality. WDRs can be issued to address both permanent and temporary discharges of a project.

The proposed project involves placement of fill materials in waters of the United States; therefore, a 401 Certification must be obtained from the Central Valley Regional Water Board.

2.1.1.3 Section 402—National Pollutant Discharge Elimination System

The 1972 amendments to the federal Water Pollution Control Act established the NPDES program to control discharges of pollutants from point-source discharges (discharges from a known source of pollutants). The NPDES program is the primary federal program that regulates point-source and non-point-source discharges (discharges from diffuse sources of pollutants) to waters of the United States.

The 1987 amendments to the CWA created a new section of the CWA devoted to storm water permitting (Section 402). EPA has granted the State of California primacy in administering and enforcing provisions of the CWA and NPDES within state boundaries. NPDES permits are issued by the State Water Board and the nine Regional Water Boards in California. General NPDES Permits cover industrial, construction, and municipal storm water discharges, and some point-source discharges for specific activities Individual NPDES Permits cover point-source discharges from wastewater facilities.

CWA Section 402 General NPDES Permits that apply to the project are the Construction General Permit and Municipal Separate Storm Sewer System (MS4) Permit requirements. Because the project involves disturbance of more than 1 acre of land, a General Construction Permit will be required. As discussed under the state requirements for the NPDES program (see Section 2.2.13), the project would comply with applicable MS4 requirements.

2.1.1.4 Section 404—Dredge/Fill Permitting

The discharge of dredged or fill material into waters of the United States is subject to permitting specified under Title IV (Permits and Licenses) of the CWA and specifically under Section 404 (Discharges of Dredge or Fill Material). Section 404 permits are administered by the USACE.

The Sacramento River is a navigable water under jurisdiction of the USACE, and the proposed project involves in-water activities. Therefore, a Section 404 Permit will be required for the project.

2.1.1.5 National Flood Insurance Program

In 1968, Congress created the National Flood Insurance Program (NFIP) in response to the rising cost of taxpayer-funded disaster relief for flood victims and the increasing amount of damage caused by floods. The NFIP makes federally backed flood insurance available for communities that agree to adopt and enforce floodplain management ordinances to reduce future flood damage. The Federal Emergency Management Agency (FEMA) manages the NFIP. FEMA creates Flood Insurance Rate Maps (FIRMs) that designate 100-year floodplain zones and delineate flood hazard areas. A *100-year floodplain zone* is an area with a one in one hundred (1%) chance of being flooded in any one year based on historical data.

The project is located within a FEMA-designated floodway and 100-year floodplain (Federal Emergency Management Agency 2012).

2.2 State Laws and Requirements

2.2.1 Porter-Cologne Water Quality Control Act

The Porter-Cologne Act, established in 1969 under Division 7 (Water Quality) of the California Water Code, complements the CWA. The Act established the State Water Board and divided the state into nine regions, each overseen by a Regional Water Board. The State Water Board is the primary state agency responsible for protecting the quality of the State's surface water and groundwater supplies—although much of its daily implementation authority is delegated to the Regional Water Boards, which are responsible for implementing CWA Sections 401, 402, and 303(d). In general, the State Water Board manages water rights and statewide regulation of water quality, while the Regional Water Boards focus exclusively on water quality within their regions.

The Porter-Cologne Act provides for development and periodic review of Water Quality Control Plans (basin plans) for each region. Basin plans identify beneficial uses of water bodies and their tributaries, and water quality objectives to protect those uses. Basin plans are implemented primarily by using the NPDES permitting system to regulate waste discharges so that water quality objectives are met. Basin plans are updated every 3 years and provide the technical basis for determining WDRs and taking enforcement actions.

Beneficial uses represent the services and qualities of a water body (i.e., the reasons the water body is considered valuable). Water quality objectives represent the standards necessary to protect and support designated beneficial uses.

The project lies within the jurisdiction of the Central Valley Water Board. The Central Valley Water Board is responsible for implementing its basin plan. The *Fourth Edition of the Water Quality Control Plan (Basin Plan) for the Sacramento River and San Joaquin River Basins* was updated in 2011 (Central Valley Regional Water Quality Control Board 2011).

2.2.1.1 State Water Resources Control Board and Regional Water Quality Control Boards

The State Water Board adjudicates water rights; sets water pollution control policy; issues Water Board Orders on matters of statewide application; and oversees water quality functions throughout the state by approving basin plans, TMDLs, and NPDES permits. The Regional Water Boards are responsible for protecting beneficial uses of water resources within their regional jurisdiction using planning, permitting, and enforcement authorities to meet this responsibility.

2.2.1.2 National Pollution Discharge Elimination System Program

Municipal Separate Storm Sewer Systems

CWA Section 402 mandates programmatic permits for municipalities to address storm water discharges, which are regulated under the NPDES General Permit for Municipal Separate Storm Sewer Systems (MS4) (MS4 Permit). Phase I MS4 regulations cover municipalities with populations greater than 100,000, certain industrial processes, or construction activities disturbing an area of 5 acres or more. Phase II (Small MS4) regulations require that storm water management plans be developed by municipalities with populations smaller than 100,000 and construction activities disturbing 1 or more acres of land area. The project would disturb more than 1 acre of land.

MS4 permits require that cities and counties develop and implement programs and measures to reduce the discharge of pollutants in storm water discharges to the maximum extent possible, including management practices, control techniques, system design and engineering methods, and other measures as appropriate. As part of permit compliance, these municipalities have created storm water management plans for their respective locations. The plans outline requirements for municipal operations, industrial and commercial businesses, construction sites, and planning and land development. These requirements may include multiple measures to control pollutants in storm water discharge. During implementation of specific projects under the program, project applicants are required to follow the guidance contained in the storm water management plans as defined by the permit holder in that location.

Because the project area is located within Caltrans, City of Sacramento, and City of West Sacramento rights-of-way (ROW), three different MS4 permits apply to the project: (1) Caltrans General NPDES MS4 Permit that covers statewide Caltrans municipal storm water discharges, (2) Sacramento County MS4 Permit for the City of Sacramento, and (3) State Water Board's Small MS4 Permit for the City of West Sacramento. These permits are discussed in more detail below.

Caltrans MS4 Permit

The State Water Board has identified Caltrans as an owner/operator of an MS4 pursuant to federal regulations. Caltrans holds a CWA Section 402 General NPDES MS4 Permit that covers primarily municipal storm water discharges within Caltrans ROW (Order No. 2012-0011-DWQ [NPDES No. CAS000003] NPDES Statewide Storm Water Permit WDRs for State of California Department of Transportation [Caltrans MS4 Permit] – effective July 1, 2013). The Caltrans MS4 Permit only covers Caltrans rights-of-way, properties, facilities, and activities in the state.

The Caltrans MS4 Permit, currently under revision, contains three basic requirements.

a. The Department must comply with the requirements of the Construction General Permit (CGP) (see below);

b. The Department must implement a year-round program in all parts of the State to effectively control storm water and non-storm water discharges; and

c. The Department storm water discharges must meet water quality standards through implementation of permanent and temporary (construction) Best Management Practices (BMPs) to the Maximum Extent Practicable, and other measures as the State Water Board determines to be necessary to meet the water quality standards.

To comply with the permit, Caltrans developed the Statewide Storm Water Management Plan (SWMP) to address storm water pollution controls related to highway planning, design, construction, and maintenance activities throughout California. The Statewide SWMP assigns responsibilities within Caltrans for implementing storm water management procedures and practices, in addition to training, public education and participation, monitoring and research, program evaluation, and reporting activities. The Statewide SWMP describes the minimum procedures and practices Caltrans uses to reduce pollutants in storm water and non-storm water discharges. It outlines procedures and responsibilities for protecting water quality, including the selection and implementation of BMPs. The proposed project will be programmed to follow the guidelines and procedures outlined in the latest Statewide SWMP in order to address storm water runoff.

Sacramento County MS4 Permit

The City of Sacramento is currently covered under Waste Discharge Requirements for the Cities of Citrus Heights, Elk Grove, Folsom, Galt, Sacramento, and County of Sacramento Stormwater Discharges from Municipal Separate Storm Sewer Systems in Sacramento County (Sacramento County MS4 Permit) (NPDES No. CAS082597; Order No. R5-2015-0023). As part of permit compliance, the Sacramento County MS4 Permitees developed a Sacramento Stormwater Quality Partnership and a Sacramento Stormwater Quality Improvement Program, which is a comprehensive program comprised of various program elements and activities designed to reduce stormwater pollution to Maximum Extent Practicable (MEP) and eliminate prohibited non-stormwater discharges through a NPDES municipal stormwater discharge permit.

The City of Sacramento's Stormwater Quality Improvement Program was established in 1990. The Program includes pollution reduction activities for construction sites, industrial sites, illegal discharges and illicit connections, new development, and municipal operations. The Program also includes an extensive public education effort, target pollutant reduction strategy and monitoring program. The Stormwater Quality Improvement Plan (SQIP) (July 2007) outlines the priorities, key elements, strategies, and evaluation methods of the City's Stormwater Management program for 2007-2011 (Sacramento Stormwater Quality Partnership 2009).

Under the Sacramento County MS4 Permit, storm water mitigation measures are required to be incorporated into project design plans for Planning Priority Projects. These include development projects (residential, industrial and commercial), parking lots, redevelopment project (or land-disturbing activity) that results in the creation, addition, or replacement of 5,000 square feet or more of impervious surface area on an already developed site, or projects located in or directly adjacent to or discharging directly to an Environmentally Sensitive Area (ESA)[1], which meet thresholds. In addition, the Sacramento Stormwater Quality Partnership developed a Hydromodification Management Plan that provides technical guidance on LID measures[2]/ hydromodification[3] strategies for the development community in the Sacramento urbanized area.

[1] A project is within a ESA if it meets one or more of the following criteria: The project is located near receiving waters designated as (1) Tributary to a Clean Water Act 303(d) Water Body, (2) RARE beneficial use, (3) Areas of Special Biological Significance (ASBS), Multiple Species Conservation Program (MSCP), any other ESA which have been identified by a County.

[2] LID are implemented to mimic a site's predevelopment hydrology by using de-centralized design techniques that infiltrate, filter, store, evaporate, and detain runoff close to the source of rainfall. Examples include bioretention facilities (rain gardens), cisterns and rain barrels, permeable pavement, bioswales, and biostrips.

[3] Hydromodification means the change in the natural watershed hydrologic processes and runoff characteristics (i.e., interception, infiltration, overland flow, interflow and groundwater flow) caused by urbanization or other land use changes that result in increased stream flows and sediment transport. In addition, alteration of stream and river channels, installation of dams and water impoundments, and excessive stream bank and shoreline erosion are also considered hydromodification, due to their disruption of natural watershed hydrologic processes.

The I Street Bridge is located adjacent to an ESA because the Sacramento River has 303(d)-listed impairments, and therefore implementation of storm water mitigation measures into the project design plan are required (Sacramento Stormwater Quality Partnership 2009). The project is not subject to hydromodification requirements, however, because projects discharging directly, through drainage channels, or through pump stations, to the Lower American River or Sacramento River will be exempt from the regulations of the HMP (Sacramento Stormwater Quality Partnership 2013).

State Water Board's Small MS4 Permit

The City of West Sacramento is designated as a Traditional Small MS4 Permittee currently covered under the State Water Resources Control Board's Phase II MS4 (Statewide Phase II MS4 Permit) (NPDES Order No. 2013-001-DWQ; General Permit No. CAS000004). This permit requires controls be implemented to reduce the discharge of pollutants in stormwater discharges to the maximum extent possible, including management practices, control techniques, system design and engineering methods, and other measures as appropriate. As part of permit compliance, the City of West Sacramento developed a Stormwater Management Program (SWMP) Planning Document in 2003. This plan outlines stormwater requirements for municipal operations, industrial and commercial businesses, construction sites, and planning and land development. These requirements may include multiple measures to control pollutants in stormwater discharge. During implementation of specific projects, project applicants will be required to follow the guidance contained in the SWMP.

Traditional permittees are required to comply with Section E of the Statewide Phase II MS4 Permit, which specifies requirements for site design measures[4], LID design standards, alternative post-construction stormwater management program, and operations and management requirements for post construction stormwater management. Under the Statewide Phase II MS4 permit, site design measures are required for all projects that create and/or replace between 2,500 square feet and 5,000 square feet of impervious surface. LID design standards are required to be implemented for all development projects that create and/or replace 5,000 square feet or more of impervious surface. If and where MS4 requirements are triggered for this project, the project will comply with all applicable permit requirements. Permittees also have to develop and implement a program to assess operation and maintenance activities and develop applicable BMPs, such as for bridge maintenance, including re-chipping, grinding, saw cutting, and painting.

[4] Site design measures are implemented to reduce site runoff. Examples of these measures include stream setbacks and buffers, soil quality improvement and maintenance, tree planting and preservation, rooftop and impervious area disconnection, porous pavement, green roofs, vegetated swales, and rain barrels and cisterns.

Construction General Permit

Construction General Permit (Order 2009-0009-DWQ as amended by Order No.2010-0014-DWQ and 2012-0006-DWQ) is a CWA Section 402 General NPDES Permit. It was adopted on November 16, 2010, became effective on February 14, 2011. The permit regulates storm water discharges from land disturbance activities of 1 acre or greater, or smaller sites that are part of a larger common plan of development. For all projects subject to the CGP, applicants are required to develop and implement an effective SWPPP.

By law, all storm water discharges associated with construction activity where clearing, grading, and excavation results in soil disturbance of at least 1 acre must comply with the provisions of the CGP. Construction activity that results in soil disturbances of less than 1 acre is subject to the CGP if there is potential for significant water quality impairment resulting from the activity as determined by the Regional Water Board. Operators of regulated construction sites are required to develop SWPPPs; to implement sediment, erosion, and pollution prevention control measures; and to obtain coverage under the CGP.

The CGP separates projects into Risk Levels 1, 2, or 3. Risk levels are determined during the planning and design phases, and are based on potential erosion and transport to receiving waters. Requirements apply according to the risk level determined. For example, a Risk Level 3 (highest risk) project would require compulsory storm water runoff pH and turbidity monitoring, and pre- and post-construction aquatic biological assessments during specified seasonal windows. A risk level assessment was done for the project and provided in Section 3.3.5.

General Waste Discharge Requirements for Low-Threat Discharges to Surface Waters

Low-threat discharges to surface waters are currently regulated by the Central Valley Regional Water Board under a regional general permit, General Waste Discharge Requirements for Discharges of Groundwater from Construction and Project Dewatering to Surface Waters in Sacramento County (Low-Threat Dewatering Permit) (Order R5-2014-0030). This permit is required if discharges occur continuously over a period of time. Otherwise, one-time surface water discharges for surface in-water work or groundwater excavation are typically covered under a 401 Certification, if one is obtained. A Notice of Intent (NOI) and Report of Waste Discharge must be submitted to the Central Valley Regional Water Board to comply with this dewatering permit. For all discharges, the permit specifies effluent limitations for total suspended solids, turbidity, biological oxygen demand, oil and grease, settleable solids, sulfides, phenols, residual chlorine, and methylene blue active substances—in addition to several other effluent limitations for specific compounds.

General Waste Discharge Requirements for Low-Threat Discharges to Land

Low-threat discharges to land are currently regulated by the State Water Board under a regional general permit, Statewide General Waste Discharge Requirements for Discharges to Land with a Low Threat to Water Quality (General Dewatering Permit for Land Discharges) (Order No. 2003–0003-DWQ). Similar to the Low-Threat Dewatering Permit, a NOI and a Report of Waste Discharge must be submitted to the Central Valley Regional Water Board to comply with this dewatering permit. Among other activities, this permit covers small temporary dewatering projects that discharge groundwater to land from small construction projects, excavation projects, or dewatering of underground utility vaults.

California Department of Fish and Wildlife Streambed Alteration Agreement

Under Chapter 6 of the California Fish and Game Code, the California Department of Fish and Wildlife (CDFW) is responsible for the protection and conservation of the State's fish and wildlife resources. Section 1602 et seq. of the code defines the responsibilities of CDFW and requires that public and private applicants obtain an agreement to "divert, obstruct, or change the natural flow or bed, channel, or bank of any river, stream, or lake designated by the department (CDFW) in which there is at any time an existing fish or wildlife resource or from which those resources derive benefit, or will use material from the streambeds designated by the department." A Streambed Alteration Agreement is required under Section 1602 of the California Fish and Game Code for all activities that involve temporary or permanent activities within State jurisdictional waters.

A Section 1602 Streambed Alteration Agreement will be required for the proposed project due to potential effects on the Sacramento River.

2.2.2 Central Valley Flood Protection Board Encroachment Permit

An encroachment permit must be obtained from the CVFPB for all proposed activities related to placement of encroachments within, under, or over the State highway rights-of-way. An *encroachment* is defined in Section 660 of the California Streets and Highways Code as "any tower, pole, pole line, pipe, pipeline, fence, billboard, stand or building, or any structure, object of any kind or character not particularly mentioned in the section, or special event, which is in, under, or over any portion of the State highway rights of way. 'Special event' means any street festival, sidewalk sale, community-sponsored activity, or community-approved activity."

Central Valley Flood Protection Act of 2008

The Central Valley Flood Protection Act of 2008 (California Water Code Section 9600) establishes the 200-year flood event as the minimum level of flood protection for urban and urbanizing areas. As part of the state's FloodSafe Program, those urban and urbanizing areas protected by flood control project levees must receive protection from the 200-year flood event level by 2025. The California Department of Water Resources (DWR) and the CVFPB collaborated with local governments and planning agencies to prepare the Central Valley Flood Protection Plan (CVFPP). The CVFPP was developed under a process implemented by the Central Valley Flood Management Program (CVFMP), which was established in 2008 to guide, manage, and implement integrated flood management actions in the Central Valley. The CVFPP, as set forth in California Water Code Section 9614, was adopted on June 29, 2012. The CVFPP proposes a "systemwide investment approach" for integrated, sustainable flood management in areas currently protected by facilities of the State Plan of Flood Control. The Public Draft 2012 CVFPP fulfills the intent and requirements of the Central Valley Flood Protection Act of 2008. The CVFPP is required to be updated every 5 years beginning in 2017.

The proposed project is located within the Lower Sacramento Regional Work Group of the CVFMP Lower Sacramento and Delta North Regional Flood Management planning area. This planning area includes the cities of Sacramento, Woodland, Davis, and Rio Vista; adjoining unincorporated areas of Yolo, Solano, Sacramento and Sutter Counties; and reclamation districts on both sides of the Sacramento River and Yolo Bypass, from the Fremont Weir to Rio Vista. Following adoption of the 2012 CVFPP, DWR launched a regional effort to help local agencies develop comprehensive regional flood management plans (RFMPs) that describe local flood management priorities, challenges, and potential funding mechanisms, as well as define site-specific improvement needs. The RFMPs present local agencies' perspectives of flood management with a prioritized list of projects that need to be implemented to reduce flood risks in each region. Each plan presents an assessment of the costs and benefits for proposed projects while considering their potential contribution to an integrated multibenefit and basin-wide solution.

Central Valley Flood Protection Board Regulations

The CVFPB exercises regulatory authority within its jurisdiction to maintain the integrity of the existing flood control system and designated floodways by issuing permits for encroachments (CCRs, Title 23, Division 1, Tier 1b Updates, and Division 1.5 – California Water Code Section 8710 et seq.). The CVFPB has mapped designated floodways along more than 60 streams and rivers in the Central Valley. In addition, Table 8.1 of the CCRs, Title 23 contains several hundred stream reaches and waterways that are regulated streams. Projects that encroach

on a designated floodway or regulated stream, or that are within 10 feet of the toe of a state-federal flood control structure (levee), require an encroachment permit and submission of an associated application, including an environmental assessment questionnaire. A project must demonstrate that it will not reduce the channel flow capacity and that it will comply with channel and levee safety requirements.

In cooperation with USACE, the CVFPB enforces standards for construction, maintenance, and protection of adopted flood control plans that will protect public lands from floods. The jurisdiction of the CVFPB encompasses the Central Valley, including all tributaries and distributaries of the Sacramento River, the San Joaquin River, and designated floodways (CCRs, Title 23, Section 2). The CVFPB has all the responsibilities and authorities necessary to oversee future modifications as approved by USACE, pursuant to assurance agreements with USACE and the USACE Operation and Maintenance Manuals (33 Code of Federal Regulations, Section 208.10; 33 U.S. Code, Section 408).

The Sacramento River (Keswick Dam to the west end of Sherman Island) is a CVFPB-designated floodway.

2.3 Regional and Local Requirements

2.3.1 City of Sacramento

2.3.1.1 Sacramento Area Flood Control Agency

The Sacramento Area Flood Control Agency (SAFCA) was formed in 1989 to address the Sacramento area's vulnerability to catastrophic flooding. This vulnerability was exposed during the record flood of 1986, when Folsom Dam exceeded its normal flood control storage capacity and several area levees nearly collapsed under the strain of the storm. In response, the City of Sacramento, the County of Sacramento, the County of Sutter, the American River Flood Control District, and Reclamation District No. 1000 created SAFCA through a Joint Exercise of Powers Agreement to provide the Sacramento region with increased flood protection along the American and Sacramento Rivers.

2.3.1.2 City of Sacramento 2035 General Plan

The following policies from the City of Sacramento 2035 General Plan (City of Sacramento 2015a) are applicable to this project with respect to hydrology and water quality.

Goal Environmental Resources (ER) 1.1. Water Quality Protection. Protect local watersheds, water bodies and groundwater resources, including creeks, reservoirs, the Sacramento and American rivers, and their shorelines.

- **ER 1.1.3 Stormwater Quality.** The City shall control sources of pollutants and improve and maintain urban runoff water quality through storm water protection measures consistent with the City's National Pollution Discharge Elimination System (NPDES) Permit.
- **ER 1.1.4 New Development.** The City shall require new development to protect the quality of water bodies and natural drainage systems through site design, (e.g., cluster development), source controls, storm water treatment, runoff reduction measures, best management practices (BMPs) and Low Impact Development (LID), and hydromodification strategies consistent with the city's NPDES Permit.
- **ER 1.1.5 Limit Stormwater Peak Flows**. The City shall require all new development to contribute no net increase in stormwater runoff peak flows over existing conditions associated with a 100-year storm event.
- **ER 1.1.6 Post-Development Runoff.** The City shall impose requirements to control the volume, frequency, duration, and peak flow rates and velocities of runoff from development projects to prevent or reduce downstream erosion and protect stream habitat.
- **ER 1.1.7 Construction Site Impacts.** The City shall minimize disturbances of natural water bodies and natural drainage systems caused by development, implement measures to protect areas from erosion and sediment loss, and continue to require construction contractors to comply with the City's erosion and sediment control ordinance and stormwater management and discharge control ordinance.

Goal Utilities 4.1 Adequate Stormwater Drainage. Provide adequate stormwater drainage facilities and services that are environmentally-sensitive, accommodate growth, and protect residents and property.

- **U4.1.1 Adequate Drainage Facilities.** The City shall ensure that all new drainage facilities are adequately sized and constructed to accommodate stormwater runoff in urbanized areas.
- **U4.1.2 Master Planning.** The City shall implement master planning programs to: Identify facilities needed to prevent 10-year event street flooding and 100-year event structure flooding; Ensure that public facilities and infrastructure are designed pursuant to approved basin master plans; Ensure that adequate land area and any other elements are provided for facilities subject to incremental sizing (e.g., detention basins and pump stations); Consider the use of "green infrastructure" and Low Impact Development.
- **U4.1.3 Regional Stormwater Facilities.** The City shall coordinate efforts with Sacramento County and other agencies in the development of regional stormwater facilities.

- **U4.1.4 Watershed Drainage Plans.** The City shall require developers to prepare watershed drainage plans for proposed developments that define needed drainage improvements per City standards, estimate construction costs for these improvements and comply with the City's National Pollutant Discharge Elimination System (NPDES) permit.
- **U4.1.6 New Development.** The City shall require proponents of new development to submit drainage studies that adhere to City stormwater design requirements and incorporate measures, including "green infrastructure" and Low Impact Development (LID) techniques, to prevent on- or off-site flooding.

Goal Environmental Constraints 2.1 Flood Protection. Protect life and property from flooding.

- **EC 2.1.11 New Development.** The City shall require evaluation of potential flood hazards prior to approval of development projects and shall regulate development in urban and urbanizing areas per state law addressing 200-year level of flood protection.
- **EC 2.1.12 New Development Design.** The City shall require new development located within a special (100-year) flood hazard area to be designed to minimize the risk of damage in the event of a flood.

2.3.1.3 River District Specific Plan

The River District Specific Plan (City of Sacramento 2011) establishes planning and design standards for redevelopment of approximately 773 acres of land located at the confluence of the American and Sacramento Rivers, north of the downtown core of the City of Sacramento. The following goal and policy related to storm water are applicable to the project.

Utility Infrastructure

Goal I1: Reduce water consumption and wastewater flows by implementing conservation techniques.

Policy I1a: Encourage the installation of techniques such as bioswales, permeable pavement, and greywater systems to reduce stormwater runoff.

2.3.1.4 Sacramento Railyards Specific Plan

The Sacramento Railyards Specific Plan (City of Sacramento 2007) addresses a 244-acre area in downtown Sacramento located immediately north of the Central Business District, east of the Sacramento River, south of North B Street, and west of the federal courthouse and the Alkali Flat neighborhood. Goals and polices from that plan that relate to hydrology and water quality are listed below.

Sustainability

Goal S-1: Maximize the use of sustainable development practices in the Plan Area.

Policy S-1.14: Encourage the installation of bio-swales to prevent stormwater runoff and further pollution of Sacramento's natural resources.

Policy S-1.15: Provide permeable surfaces wherever possible to prevent stormwater runoff.

Policy S-1.17: Reduce stormwater runoff through the capture and re-use of rainwater.

Utilities and Community Services

Goal CS-2: Provide for the sanitary sewage needs of the project while facilitating the City in complying with standards established by the City's NPDES permit with the Regional Water Quality Control Board.

Policy CS-2.2: Offset the increased sanitary sewer flows into the combined sewer system through on-site detention of storm water flows, and discharge of retained storm water to the Sacramento River.

Goal CS-3: Provide a storm drainage system to serve the Plan Area that achieves the water quality provisions of the City's municipal NPDES Stormwater Permit.

Policy CS-3.1: Provide for the separation of combined storm and sanitary sewer flows in the Plan Area.

Policy CS-3.2: Design the storm drainage system to meet the design criteria of the City's Department of Utilities, Sacramento City design standards and the terms of the City's NPDES permit.

2.3.1.5 City of Sacramento Stormwater Management and Control Code

The City Stormwater Management and Control Code (Chapter 13.16 of the City Code) is intended to control non-storm water discharges to the storm water conveyance system; eliminate discharges to the storm water conveyance system from spills, dumping, or disposal of materials other than storm water; and reduce pollutants in urban storm water discharges to the maximum extent practicable. Non-storm water discharges are prohibited except where the discharge is regulated under an NPDES permit. Discharges from specified activities that do not cause or contribute to the violation of any plan standard, such as landscape irrigation and lawn watering and flows from fire suppression activities, also are exempt from this prohibition. Discharges of pumped groundwater not subject to an NPDES permit may be permitted to discharge to the

storm water conveyance system upon written approval from the City and in compliance with the City's conditions of approval.

2.3.1.6 City of Sacramento Grading, Erosion, and Sediment Control Ordinance

The City of Sacramento Grading, Erosion, and Sediment Control Ordinance (Title 15, Chapter 15.88 of the City Code) sets forth rules and regulations to control land disturbances, landfill, soil storage, pollution, and erosion and sedimentation resulting from construction activities. With limited exceptions, grading approval must be received from the City Department of Utilities before construction. All project applicants, regardless of project location, are required to prepare and submit separate erosion and sediment control plans applicable to the construction and post-construction periods. The ordinance also specifies other requirements, such as written approval from the City for grading work within the right-of-way of a public road or street, or within a public easement.

2.3.1.7 Sacramento Stormwater Quality Improvement Plan

The Sacramento Stormwater Management Program is a comprehensive program comprised of various program elements and activities designed to reduce storm water pollution to the maximum extent practicable and eliminate prohibited non-storm water discharges in accordance with federal and state laws and regulations. These laws and regulations are implemented through NPDES municipal storm water discharge permits. In 1990, the County of Sacramento and the Cities of Sacramento, Citrus Heights, Elk Grove, Folsom, Galt, and Rancho Cordova, collectively known as the Sacramento Stormwater Quality Partnership (Partnership), applied for and received one of the first areawide NPDES MS4 storm water permits in the country and began development of core storm water management program elements and activities to address local urban runoff water quality problems. As part of the program, a SQIP (City of Sacramento 2009) was prepared in compliance with the MS4 Permit as a comprehensive plan that describes the Partnership's Stormwater Management Program.

2.3.2 City of West Sacramento

2.3.2.1 West Sacramento Area Flood Control Agency

The City of West Sacramento and Reclamation Districts 900 and 537 make up the joint powers authority that forms the West Sacramento Area Flood Control Agency (WSAFCA). WSAFCA's mission is to plan and build flood risk reduction facilities that protect the City of West Sacramento's residents and property. WSAFCA is also the regional floodplain administrator carrying out duties associated with floodplain management and flood preparedness activities.

2.3.2.2 City of West Sacramento General Plan

The City of West Sacramento General Plan (City of West Sacramento 2008) was adopted in 1990 and is currently undergoing an update. The plan has been amended several times since 1990, and the current 2008 version outlines the following key goals and policies that relate to hydrology and water quality.

Public Facilities and Services Element

Goal C: To maintain an adequate level of service in the City's storm drainage system to accommodate runoff from existing and future development and to prevent property damage due to flooding.

Policy 1. Where practical and economical, the City shall upgrade existing drainage facilities as necessary to correct localized flooding problems.

Policy 2. The City shall continue to expand and develop storm drainage facilities to accommodate the needs of existing and planned development.

Policy 4. The City shall, through a combination of drainage improvement fees and other funding mechanisms, ensure that new development pays its fair share of the costs of drainage system improvements

Policy 5. The City shall cooperate with other responsible agencies in ensuring that levees surrounding the city are maintained and improved to provide a minimum 200-year flood protection.

Natural Resources Element

Goal A: To protect water quality in the Sacramento River, Sacramento Deep Water Ship Channel, Lake Washington, and the area's groundwater basin.

3. The City shall not approve new development that has a significant potential for adversely affecting water quality in the Sacramento River, the Deep Water Ship Channel, Lake Washington, or the area's groundwater basin.

5. The City shall utilize the CEQA process to identify and avoid or mitigate potential groundwater pollution problems resulting from new commercial and industrial development.

7. The City shall implement measures to minimize the discharge of sediment into its watercourses.

Health and Safety

Goal B: To prevent loss of life, injury, and property damage due to flooding.

Policy 1. The City shall continue to participate in the National Flood Insurance Program. To this end, the City shall ensure that local regulations are in full compliance with standards adopted by the Federal Emergency Management Agency.

Policy 5. New development shall be designed to prevent the diversion of floodwaters onto neighboring parcels.

2.3.2.3 Washington Specific Plan

The Washington Specific Plan (City of West Sacramento 1996) defines a vision for redeveloping the 194-acre urban area of West Sacramento bounded by Tower Bridge Gateway, the Sacramento River, A Street, and portions of 6th and 8th Street. Key goals and policies that relate to hydrology and water quality are found in the Public Facilities and Services section and are the same as those in the City of West Sacramento General Plan (see above).

2.3.2.4 City of West Sacramento Municipal Code

The following regulations of the City's Municipal Code regarding hydrology and water quality are applicable to the project.

Title 13, Public Services, Chapter 13.10—Urban Stormwater Quality Management and Discharge Control

This chapter contains the following regulations and requirements to prevent, control, and reduce stormwater pollutants:

13.10.130—requirement to prevent, control, and reduce stormwater pollutants;

13.10.140—compliance with BMPs;

13.10.150—requirement to eliminate illegal discharges;

13.10.170—watercourse protection;

13.10.180—damage to the storm drain system;

13.10.190—requirement to remediate;

13.10.200—requirement to monitor and analyze;

13.10.210—containment and notification of spills;

13.10.220—authority to inspect;

13.10.230—authority to sample, establish sampling devices, and test; and

13.10.240—City inspection of stormwater conveyance system.

Title 15—Buildings and Construction

Chapter 15.08, Grading, establishes standards for the preparation of sites and construction activities to protect the health, safety and general welfare of the public by protecting against unwarranted or unsafe grading, drainage works or other aspects of site development. The following provisions in Chapter 15.08 are applicable:

15.08.180 Erosion control: Contains basic design principles and standards that shall be incorporated in grading operations to control erosion and reduce sedimentation.

15.08.280 Runoff control: Contains performance standards for a surface runoff control plan if required by the City manager or designee.

15.08.300 Environmental standards: Contains compliance requirements for CEQA and other environmental laws.

Chapter 15.50, 200 Year Flood Protection, includes the following requirements for 200-year flood protection:

15.50.060 No building permit until compliance demonstrated:

> No building permit shall be issued in connection with the construction of any new structure until the applicant for the building permit demonstrates to the satisfaction of the floodplain administrator that: (1) prior to occupancy, the structure will have 200 year flood protection; and (2) any improvements constructed or measures implemented by the applicant to ensure 200-year flood protection will not significantly increase the risk of flooding or the effect of flooding on any adjacent or nearby properties. An applicant shall demonstrate compliance either by the construction of flood management improvements or other mitigation measures beyond those set forth in Title 18, or the payment to the City of an in-lieu flood management fee established by resolution of the City Council. The fees shall be paid at the time of issuance of building permits.

15.50.080 Integration with Title 18: Contains requirements for coordination with Title 18 below. In the event of any conflict, the more stringent requirements will apply.

2.3.2.5 City of West Sacramento Urban Stormwater Quality Management and Discharge Control Ordinance

The City's Grading, Erosion, and Sediment Control Ordinance (Title 13, Chapter 13.10 of the City Code) sets forth rules and regulations to protect and promote the health, safety, and general welfare of the citizens of the city by controlling non-storm water discharges to the storm water conveyance system, by eliminating discharges to the storm water conveyance system from spills, dumping, or disposal of materials other than storm water, and by reducing pollutants in urban storm water discharges to the maximum extent practicable.

2.3.2.6 City of West Sacramento Stormwater Management Program Planning Document

The City of West Sacramento developed the Stormwater Management Program Planning Document (2003) to address storm water quality within the City's jurisdiction. The SWMP addresses a wide variety of activities conducted in urbanized areas of the City that are sources of pollutants in storm water. This planning document was developed to comply with the State Water Board's Small MS4 General Permit.

Chapter 3 Affected Environment

3.1 Introduction

Hydrology and water quality are affected by climatological conditions, topography, and the types and amounts of pollutants discharged. This chapter describes regional existing hydrology and water quality conditions in the project vicinity as well as local existing hydrology and water quality conditions in the immediate project area.

3.2 General Setting

3.2.1 Population and Land Use

The I Street Bridge is a bridge crossing over the Sacramento River between the West Sacramento to the west, and Sacramento to the east. Both the City of Sacramento and City of West Sacramento are located in the northern portion of the Central Valley, at the confluence of the American River and Sacramento River. The City of Sacramento is located in Sacramento County, and the City of West Sacramento is located in Yolo County. As reported by the 2010 Census, the population of the City of Sacramento was 466,488, and that of the City of West Sacramento was 48,744 (U.S. Census 2010).

The immediate project area is characterized by the Sacramento River, vegetated levee banks, and land uses on either side of the river. Primarily industrial and vacant land uses are located east of the river, and suburban residential and commercial land uses are located to the west. The project site is not located near a state scenic highway or other designated scenic corridor (California Department of Transportation 2015).

3.2.2 Topography

The project is located in the northern portion of the Central Valley, called the Sacramento Valley, which drains into the Sacramento-San Joaquin River Delta (the Delta). The valley boundaries are Lake Shasta to the north, the Coast Ranges to the west, the Sierra Nevada to the east, and the Delta to the south. The valley floor itself is relatively flat with exception of the Sutter Buttes. (Ceres 2014).

The project site is relatively flat. Based on the Natural Resources Conservation Service (NRCS) soil unit map, slopes within the project area are 0–2% (Natural Resources Conservation Service 2015). Therefore, a 1% slope was assumed for this WQAR.

3.2.3 Hydrology

Regional Hydrology

The project is located in the Sacramento River Basin, which has a total drainage area of approximately 27,000 square miles. Within the basin, the project site is located within the Lower Sacramento Valley Watershed. The basin drains the eastern slopes of the Coast Ranges, Mount Shasta, the western slopes of the southernmost region of the Cascades, and the northern portion of the Sierra Nevada. The Sacramento Valley Watershed is approximately 5,500 square miles (Sacramento River Watershed Program 2010). Figure 3 shows watersheds and hydrological features within the project vicinity.

According to the U.S. Geological Survey National Watershed Boundary Dataset, the project area lies within three hydrologic units. The eastern bridge landing and Sacramento River are within Lake Greenhaven-Sacramento River [Hydrologic Unit Code (HUC) 180201630701]. On the western landing, the area north of I Street is within Tule Canal-Toe Drain (HUC 180201630302), and the area south of I Street is within Toe Drain-Cache Slough (HUC 180201630606). (U.S. Geological Survey 2015).

Local Hydrology

Precipitation and Climate

The climate of Sacramento is Mediterranean, which is characterized as damp to wet mild winters and hot, dry summers. The rainy season generally occurs between October and April, and the total average annual rainfall is 17.59 inches (Table 4). (Western Regional Climate Center 2015a).

Table 2. Month Average Precipitation at the Sacramento Executive Airport

Monthly Average Total Precipitation (inches)												Total Annual
Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec	
3.56	3.03	2.50	1.28	0.54	0.16	0.02	0.05	0.24	0.95	2.10	3.06	17.59

Source: Western Regional Climate Center 2015a

The annual mean temperature is 61.0 °F, with the monthly daily average temperature ranging from 46.4 °F in December to 75.5 °F in July. Summer heat is generally moderated by the “Delta breeze” coming from the Delta and ultimately the San Francisco Bay, and temperatures cool down sharply at night. (Western Regional Climate Center 2015b.)

Figure 3
Watersheds and Hydrological Features within the Project Vicinity

Surface Streams

Sacramento River

The I Street Bridge crosses the Sacramento River at approximately 0.75 mile downstream of its confluence with the American River. The Sacramento River is the largest river in California. The Sacramento River carries 31% of the State's total surface water runoff. Primary tributaries to the Sacramento River are the Pit, Feather, and American Rivers. The headwaters of the Sacramento River are in the Klamath Mountains in northern California; the river flows 445 miles before joining the San Joaquin River 40 miles south of the City of Sacramento, which ultimately flows to San Francisco Bay.

The Sacramento River, beginning at the I Street Bridge, falls within the legal description of the Delta (California Department of Water Resources 1995). Before development of the Sacramento area, the river had a wide natural floodplain. Today, the river is heavily altered, with hydroelectric and water supply impoundments throughout the course of the river and a network of flood control levees through populated areas. (Sacramento River Watershed Program 2015.)

The preliminary results of the wetland delineation for the project indicate that the location of the ordinary high water mark (OHWM) in the Sacramento River was based on the elevation of 19 feet National Geodetic Vertical Datum (NGVD), or mean sea level, that was previously determined by the USACE at the I Street Bridge. Observations in the field further confirmed this location based on the presence of shelving, silt deposition, and wracking[5]. The average width of the Sacramento River at the OHWM is approximately 672 feet. The channel bottom is a natural substrate, presumably sand and sediment, but water turbidity makes visual confirmation of the composition difficult. The river banks are mostly steeply sloped and support riparian forest vegetation, with rip-rap near the bottom of the slope. (ICF International 2015a).

American River

The headwaters of the American River are the Sierra Nevada; the river flows 119 miles until converging with the Sacramento River. Similar to the Sacramento River, the American River is heavily modified by dams and diversions for hydroelectricity and irrigation demands. (U.S. Geological Survey 2015.)

The Lower American River originates from Folsom Lake, a man-made reservoir created by Folsom Dam 30 miles east of Sacramento. Folsom Lake is a multipurpose reservoir that stores water for irrigation; domestic, municipal, and industrial use; hydropower; recreation; water

[5] Wracking typically refers to lines of debris from past materials piled up on along the channel banks.

quality; and fisheries flows. Nimbus Dam, 7 miles downstream from Folsom Dam, stores water from Folsom Dam hydropower releases and re-regulates them via releases to provide for a steady flow downstream in the American River. This allows the release of water from Folsom Dam for power generation to fluctuate with daily power demands. The Lower American River has levees on its north and south banks for about 13 miles from the Sacramento River to Carmichael on the north end. Portions of the floodplain have been acquired by the City or County of Sacramento and are managed cooperatively as the American River Parkway. (Sacramento River Watershed Program 2015).

Storm Drainage System

The City of Sacramento owns and operates a combined sewer system (CSS) that conveys domestic and commercial wastewater and storm water runoff from downtown Sacramento, East Sacramento, and Land Park areas. The City of Sacramento also owns and operates a separate sanitary sewer system that conveys domestic and commercial wastewater from parts of the city surrounding the CSS to the north, east, and south; the storm water is carried and discharged directly into local waterways within the Lower Sacramento River watershed. In the City of West Sacramento, storm water from north of Interstate 80 (I-80) is carried through a system of both surface ditches (in more residential areas) and pipes (in more commercial areas). Approximately 95% of the water (Harbor, Riske, Washington, and 5th Street pump stations) is then discharged (pumped) into the Yolo Bypass. Approximately 5% of the water (Lighthouse and Raley pump stations) is discharged into the Sacramento River. (City of West Sacramento 2003.)

The project area is served by the City of Sacramento's CSS to the Sacramento River, as well as a separate storm water system on the east side of the bridge and the City of West Sacramento's separate storm water system to the Yolo Bypass.

Floodplains

As shown in Figure 4, the eastern side of the I Street Bridge is located within 100-year Flood Zone AE. This zone is a FEMA-identified Special Flood Hazard Area (SFHA), an area subject to flooding during the 100-year storm event (1% annual chance of flooding) (Federal Emergency Management Agency 2012). The western side of the channel is protected from the 100-year flood by levees. Development in an SFHA is regulated by federal, state, and local agencies. Flood Zone AE applies to the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood elevations. The landings (or approaches) of the I Street Bridge are outside of the 100-year FEMA flood zone. They are within a Zone X (unshaded) or Zone C, which are areas subject to minimal flooding that are outside the 500-year flood zone (Federal Emergency

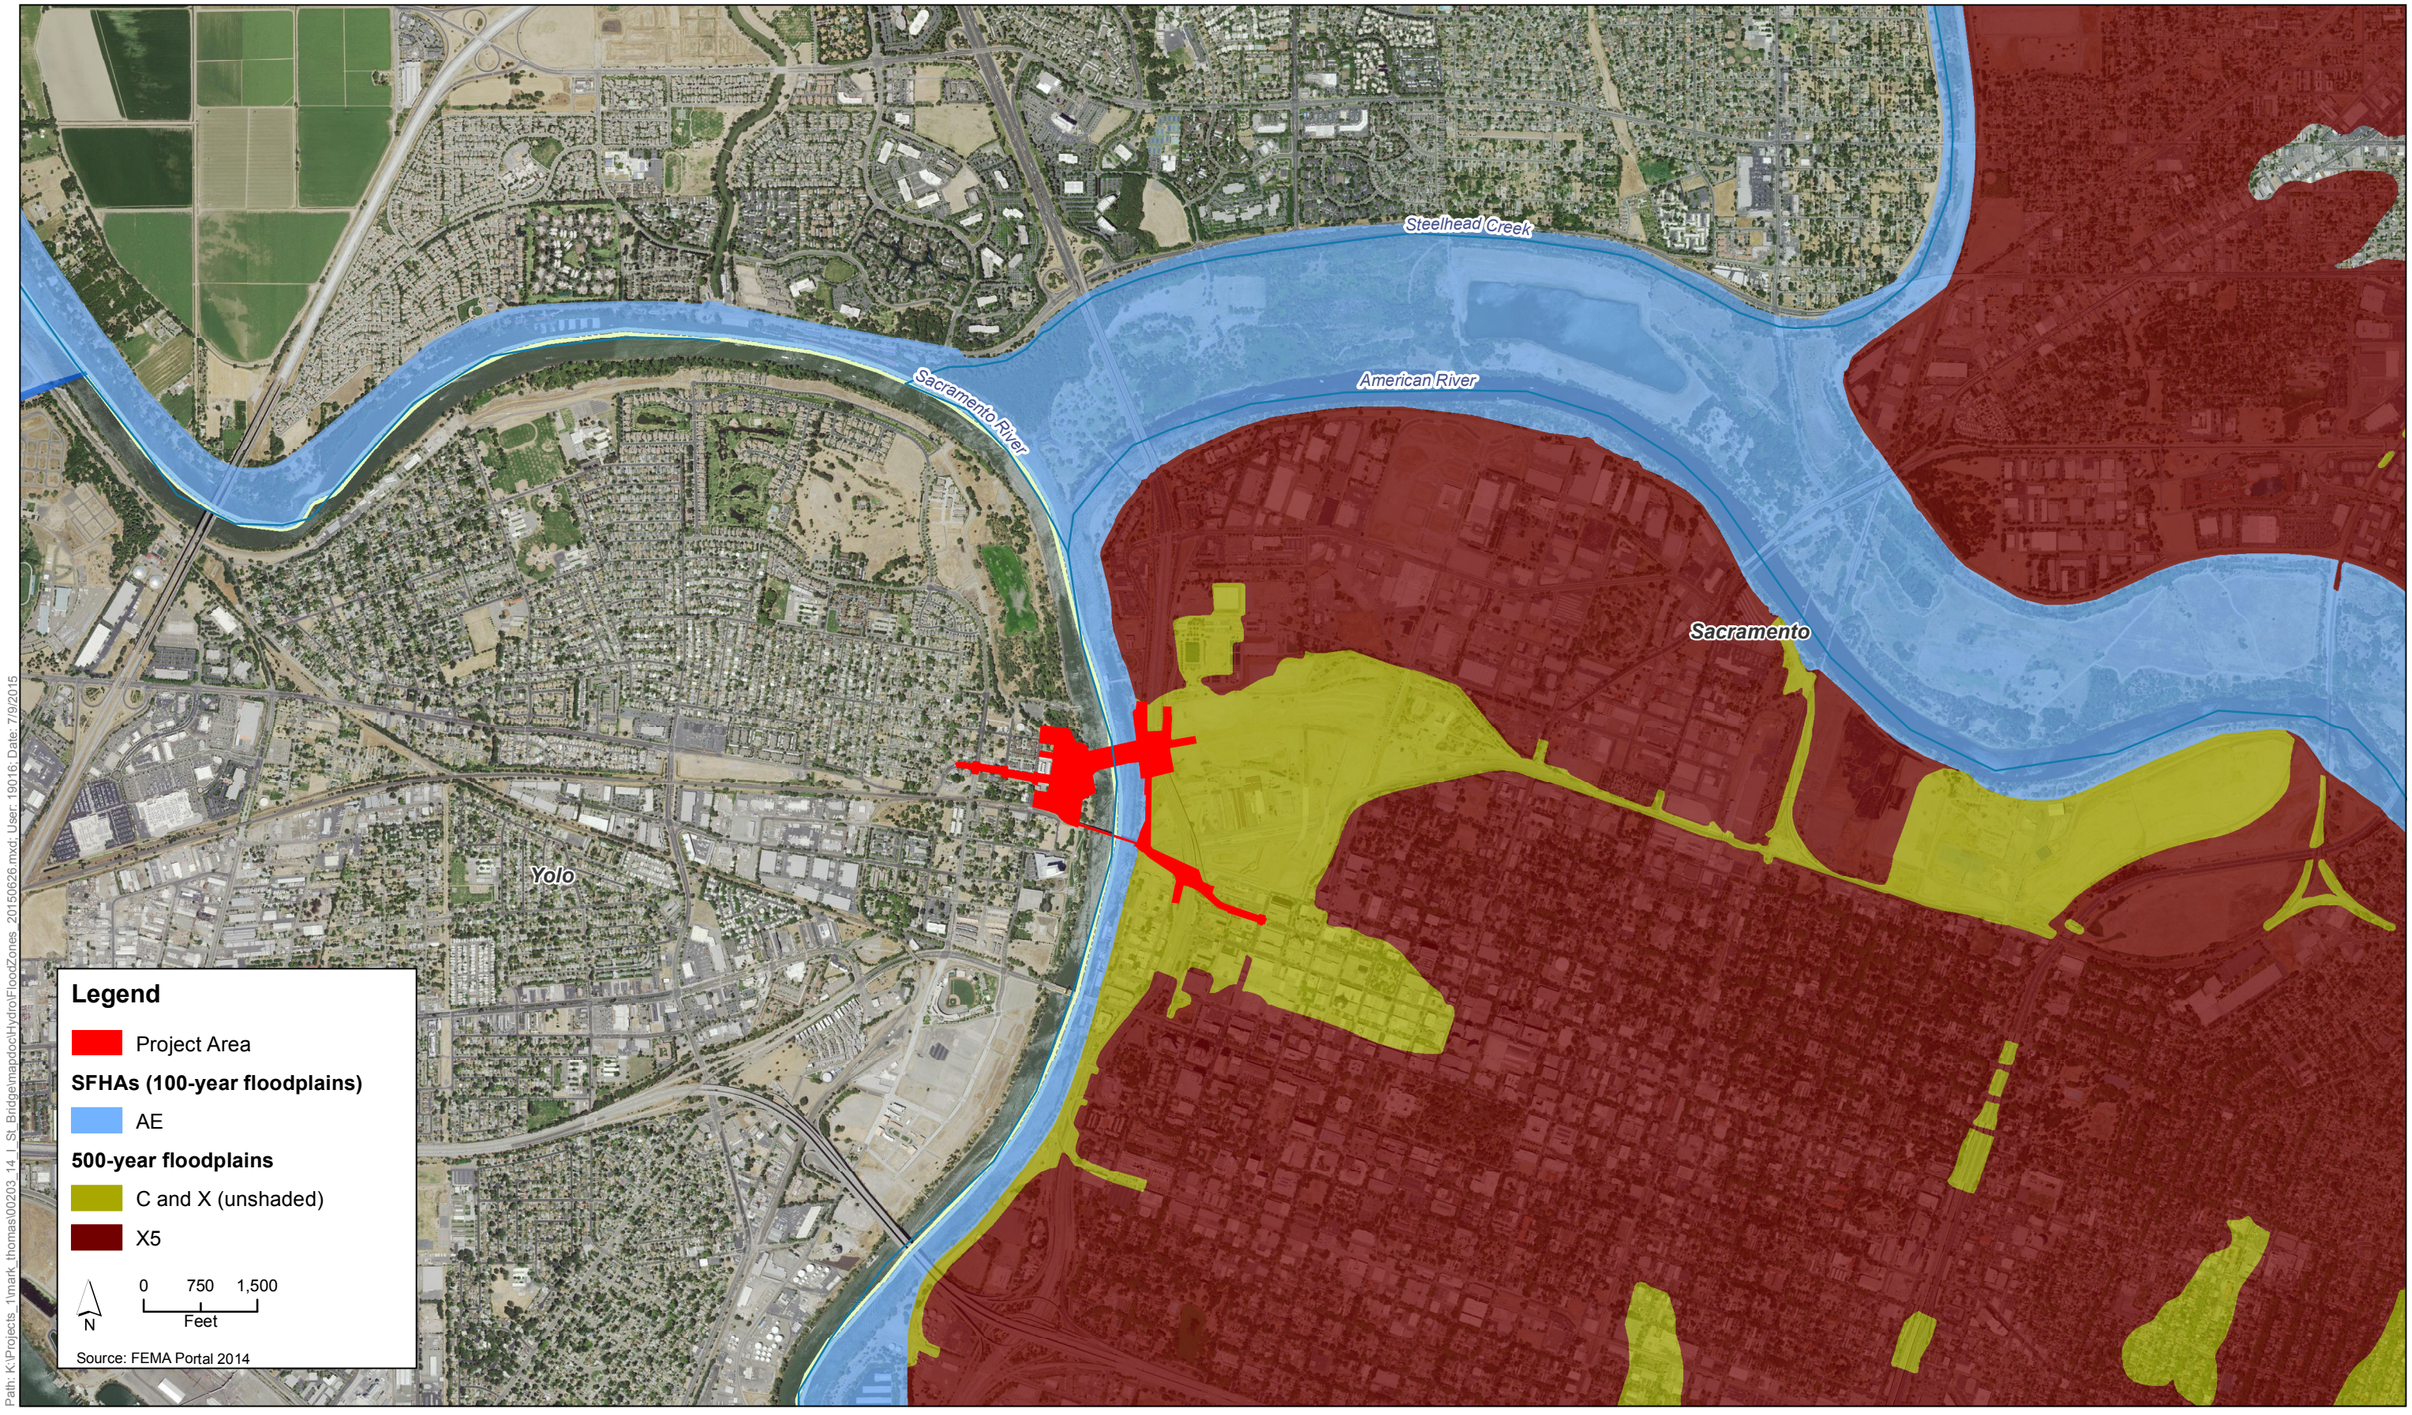

Figure 4
FEMA Flood Zones within the Project Vicinity

Management Agency 2012). The surrounding area on the eastern end is designated as Flood Zone X5, which is a 500-year flood zone. Descriptions of flood zone designations are provided in Table 3.

Table 3. FEMA Flood Zone Designations in the Project Vicinity

Zone	Zone Description
AE	Areas with a 1 percent annual chance of flooding. Base flood elevations are determined and shown on Federal Emergency Management Agency flood maps.
X (unshaded) or C	Area of minimal flood hazard, usually depicted on Flood Insurance Rate Maps as above the 500-year flood level. Zone C may have ponding and local drainage problems that do not warrant a detailed study or designation as base floodplain. Zone X is the area determined to be outside the 500-year flood and protected by levee from the 100-year flood.
X5	An area inundated by 500-year flooding; an area inundated by 100-year flooding with average depths of less than 1 foot or with drainage areas less than 1 square mile; or an area protected by levees from 100-year flooding.

Source: Federal Emergency Management Agency 2012

As required by the CVFPB, levees within urban areas of the Central Valley need to be able to provide for a 200-year flood event level of protection. The proposed project is located within the Lower Sacramento Regional Work Group of the CVFMP Lower Sacramento and Delta North Regional Flood Management planning area. The Lower Sacramento and Delta North Regional Working Group has branded itself as FloodProtect and released their RFMP in July 2014.

Both Sacramento and West Sacramento have a history of serious flooding, beginning in the 1800's when the City of Sacramento was founded and continuing until the 1986 Folsom Dam flood. Prior to development, the area would have been flooded by seasonal runoff every year. Following the population growth in the area, flood control levees, weirs, and dams were constructed to protect the area from flooding. SAFCA is the responsible agency for maintaining flood protection along the American and Sacramento Rivers. (California Department of Water Resources 2010).

The Lower Sacramento River/Delta North Flood Management Planning Region contains a number of flood control facilities—both locally-owned and operated and State-owned and operated through the State Plan of Flood Control (SPFC). The closest SPFC facility to the project site is the Sacramento Weir, located on the Sacramento River just upstream of the confluence of the Sacramento and American Rivers. This structure allows excess water to be discharged into the Yolo Bypass via the Sacramento Bypass and to reduce pressure on downstream levees during high flows. Both the Sacramento and American Rivers are surrounded by SPFC levees. The Sacramento River Bank Protection Project (SRBPP) was initiated to evaluate the levees bordering the river and reduce stream bank erosion along the levees to minimize the threat of a

flood along the Sacramento River. The USACE, Sacramento District is responsible for implementation of the project in conjunction with its non-federal partner, the CVFPB.

Municipal Supply

City of Sacramento drinking water comes from two main sources: surface water from the American and Sacramento Rivers (84% of total supply) and groundwater (16% of total supply). Sacramento has two intake structures, one located on the American River and one located on the Sacramento River. Each feeds water to the E.A. Fairbairn Water Treatment Plant on the American River and the Sacramento River Water Treatment Plant on the Sacramento River. (City of Sacramento 2015.)

Similarly, the main source of drinking water for the City of West Sacramento is the Sacramento River. The surface water intake structure is located at Bryte Bend upstream of the confluence of the Sacramento and American Rivers. In addition to surface water, the City of West Sacramento operates two groundwater wells that primarily provide water during emergencies, such as drought periods. Water is treated to drinking water quality at the George Kristoff Water Treatment Plant (previously known as the Bryte Bend Water Treatment Plant). (City of West Sacramento 2010.)

Many groundwater wells exist within the basin, and most are used to supply individual domestic demands or small agricultural operations. The basin has an extensive system of both shallow and deep aquifers, which the county depends on for domestic and agricultural water supply. Recent droughts indicate that water supplies in the Sacramento Valley are vulnerable to overdraft.

Groundwater Hydrology

Regional Groundwater Hydrology

The project site is within the larger Sacramento Valley Groundwater Basin. Each approach (or landing) of the I Street Bridge is located within a different subbasin. The eastern landing of the I Street Bridge is within the South American Subbasin, whereas the western landing is within the Yolo Subbasin.

The South American Subbasin is bounded on the east by the Sierra Nevada, on the west by the Sacramento River, on the north by the American River, and on the south by the Cosumnes and Mokelumne Rivers. The subbasin is recharged by subsurface inflow from American River percolation and by precipitation on the valley floor. Groundwater levels declined consistently from the 1960’s to 1980’s but have since recovered, except for some wells within the vicinity of the City of Sacramento (California Department of Water Resources 2004).

Several sites of significant groundwater quality impairment are within the South American Subbasin, including three EPA Superfund sites: Aerojet, Mather Field, and the Sacramento Army Depot. Other sites with groundwater quality impairment are the Kiefer Boulevard Landfill, an abandoned Pacific Gas & Electric Company site on Jibboom Street near Old Sacramento, and the Southern Pacific and Union Pacific Rail Yards in downtown Sacramento, which is located adjacent to the project site. (California Department of Water Resources 2004).

The Yolo Subbasin is bounded on the east by the Sacramento River, on the west by the Coast Ranges, on the north by Cache Creek, and on the south by Putah Creek. Similar to the South American Subbasin, the subbasin is recharged by subsurface inflow from American River percolation and by precipitation on the valley floor. During periods of drought, groundwater levels decline, but long-term trends do not indicate any significant decline in water levels—except for localized pumping depressions in the vicinity of the Davis, Woodland, and Dunnigan/Zamora areas (California Department of Water Resources 2004).

Groundwater quality in the Yolo Subbasin is generally considered to be good for both agricultural and municipal uses, even though the water is hard to very hard overall. (California Department of Water Resources 2004).

The primary source of groundwater recharge for both subbasins is applied irrigation water and direct rainfall. Recharge of aquifers typically occurs along the streambeds of creeks and canals. Recharge occurs naturally and also through reservoir releases, which can be used as effective conjunctive water use facilities to minimize groundwater overdraft and land subsidence.

Local Groundwater Hydrology

Groundwater is expected to vary seasonally. Groundwater was encountered during previous drilling explorations at a depth of approximately 15 to 25 feet below the ground surface (an elevation ranging from approximately 0 to 5.5 feet NAVD88[6] (GEI Consultants 2014).

Groundwater levels can vary over time in response to environmental, seasonal, and land use changes. For this reason, groundwater levels at the time of construction or in the future could differ from those indicated in previous boring logs (GEI Consultants 2014).

[6] The North American Vertical Datum of 1988. It is a datum used for mean sea level elevations that uses tidal bench marks from Canada, United States and Mexico.

3.2.4 Geology/Soils

3.2.4.1 Regional Geology/Soils

Sacramento and the project site are situated within the Great Valley geomorphic province of California. The Great Valley is a gently-sloping to flat alluvial plain east of the Coast Ranges and west of the Sierra Nevada. It is a northwest-trending structural trough that was formed by the westward tilting of the Sierra Nevada block.

3.2.4.2 Local Geology/Soils

The general vicinity of the project site is reclaimed land that was filled-in in during the 1860's and 1900's. The magnitude of fill material that was placed at that time is unknown (GEI Consultants 2014). According the NRCS Web Soil Survey, the upper 5 feet of the project site is underlain by soils assigned to the following types (Natural Resources Conservation Service 2015; GEI Consultants 2014; ICF International 2015a).

- Orthents-Urban land complex, 0 – 2% slopes (Sacramento County)
- Urban land (Sacramento County)
- Lang sandy loam (Yolo County)
- Lang sandy loam, deep (Yolo County)
- Sycamore silt loam (Yolo County)

Based on the Preliminary Geotechnical and Foundation Report for the project (GEI Consultants 2014), the structure and composition of subsurface soils along the west end of the river embankment were sampled during levee evaluations on the crest and in the vicinity of the West Sacramento levee. The analysis found approximately 15 feet of loose sand and silt in the embankment, which was underlain by an approximately 9-foot layer of clay, followed by an approximately 16-foot layer of sandy silt, and then a 35-foot layer of sand and silt. On the east end of the river embankment, core samples found approximately 6 feet of loose sand with silt underlain by approximately 10 feet of loose sand, followed by approximately 50 feet of sand and silt, which was underlain by an approximately 23-foot layer of medium-dense to very-dense gravel, followed by a clay layer.

3.2.4.3 Soil Erosion Potential

Extensive erosion has occurred from the Sacramento and American Rivers and other tributaries that run across the Central Valley toward the Delta (Ceres 2014). The banks of the Sacramento River channel are particularly vulnerable to erosion during high winter flows. In 1960, the

SRBPP was authorized to help prevent erosion of the Sacramento River banks. The SRBPP evaluates the levees bordering the river to reduce stream bank erosion along the levees and minimize the threat of a flood along the Sacramento River. The USACE, Sacramento District is responsible for implementation of the SRBPP in conjunction with its non-federal partner, the CVFPB. (U.S. Army Corps of Engineers 2015.)

Erosion factor K indicates the susceptibility of a soil to sheet and rill erosion by water. Factor K is one of six factors used in the Universal Soil Loss Equation (USLE) and the RUSLE to predict the average annual rate of soil loss by sheet and rill erosion, in tons per acre per year. The estimates are based primarily on percentage of silt, sand, and organic matter and on soil structure and saturated hydraulic conductivity (Ksat). Values of K at the project site range from 0.02 to 0.69. Other factors being equal, the higher the value, the more susceptible the soil is to sheet and rill erosion by water. The weighted average soil erodibility K factor for the soils at the project site is 0.27 (U.S. Department of Agriculture 2015) (see Attachment A). Therefore, the potential for erosion at the site is moderate.

3.2.5 Biological Communities

Historically, the Sacramento River was home to a multitude of avian and aquatic species. Development has drastically reduced the size of these populations. Today, the Sacramento River Basin continues to provide habitat for a variety of fish and wildlife but not at the same population sizes as historical conditions. This section provides an overview of existing biological resources in the project vicinity. More details on biological resources can be found in the Natural Environment Study (NES) for the project (ICF International 2015a).

The health of the Sacramento River and its tributaries is critical for the survival of anadromous fish species such as Chinook salmon, steelhead, and sturgeon. Rivers and streams in the upper watersheds are vital for coldwater fish such as native trout. Located along the Pacific Flyway, the marshlands in the Sacramento Valley continue to be an important stop for migrating waterfowl. Both migratory and resident species rely on the state and federal wildlife refuges that exist throughout the Sacramento Basin and on the vast area of irrigated agricultural land.

The Yolo Bypass Wildlife Area is the closest wildlife refuge. It is approximately 7 miles southwest of the proposed project, on I-80 at the Yolo Causeway between Davis and Sacramento.

3.2.5.1 Aquatic Habitat

Special-Status Species

Table 4 presents the special-status aquatic species that could be found in the project vicinity. Currently, no field assessments or surveys have been conducted at the project site to determine whether suitable habitat for these species exists at the site.

Table 4. Federal Endangered and Threatened Species That Occur in or May Be Affected by Projects in the Project Vicinity

Common Name	Scientific Name
Fish	
Green sturgeon	*Acipenser medirostris*
Delta smelt	*Hypomesus transpacificus*
Central Valley steelhead	*Oncorhynchus mykiss*
Central Valley spring-run Chinook salmon	*Oncorhynchus tshawytscha*
Central Valley winter-run Chinook salmon	*Oncorhynchus tshawytscha*
Invertebrates	
Vernal pool fairy shrimp	*Branchinecta lynchi*
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*
Vernal pool tadpole shrimp	*Lepidurus packardi*
Amphibians	
California tiger salamander	*Ambystoma californiense*
California red-legged frog	*Rana draytonii*
Reptiles	
Giant garter snake	*Thamnophis gigas*
Birds	
Western yellow-billed cuckoo	*Coccyzus americanus occidentalis*
Least Bell's vireo	*Vireo bellii pusillus*

Source: U.S. Fish and Wildlife Service 2014

Stream/Riparian Habitats

Riparian habitat exists on both the eastern and western banks of the Sacramento River. At this time, this area has not been surveyed, but aerial images confirm the presence of vegetated streambanks.

Wetlands

According to the U.S. Code of Federal Regulations, Title 40, Part 230, entitled "Section 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material," *special aquatic sites* are defined as the following.

- Sanctuaries and refuges
- Wetlands

- Mud flats
- Vegetated shallows
- Coral reefs
- Riffle and pool complexes

At this time, a survey of the project area has not been conducted, but there is a potential for shallow vegetated wetlands to exist along the banks of the river.

Fish Passage

To comply with Senate Bill 857, a fish passage assessment will be conducted at the project site and will be submitted to CDFW. Any structures blocking anadromous fish passage will be identified immediately to the project engineer for possible design modifications and/or remediation. Modifications and/or remediation on any structures blocking anadromous fish passage will be conducted in accordance with *Fish Passage Design for Road Crossings, an Engineering Document Providing Fish Passage Design Guidance for Caltrans Projects* (California Department of Transportation 2007).

3.3 Water Quality Objectives/Standards and Beneficial Uses

3.3.1 Surface Water Quality Objectives/Standards and Beneficial Uses

Beneficial uses represent the services and qualities of a water body (i.e., the reasons the water body is considered valuable). Water quality in a typical surface water body is influenced by processes and activities that take place within the watershed. Because of the urbanized nature of the project vicinity, surface water quality in the project area is directly affected by storm water runoff from adjacent streets; highways; and properties using fertilizers, pesticides, metals, hydrocarbons, and other pollutants. Typically, pollutant levels in the ocean are highest following the first storm flows of the season, when constituents accumulated during the dry season are flushed into the river.

The Central Valley Regional Water Board has delineated region-wide and water body-specific beneficial uses, and has set numeric and narrative water quality objectives for several substances and parameters in numerous surface waters in its region. Beneficial uses for the Sacramento River are designated in the Central Valley Regional Water Board Basin Plan (Central Valley Regional Water Quality Control Board 2011), as shown in Table 5.

Table 5. Designated Beneficial Uses for the Sacramento River

Water Body	Designated Beneficial Use
Sacramento River (Colusa Basin Drain to I Street Bridge)	Municipal and domestic supply, agricultural (irrigation), contact recreation, non-contact recreation, warm freshwater habitat, cold freshwater habitat, warm freshwater fish migration, cold freshwater fish migration, warm freshwater fish spawning, cold freshwater fish spawning, wildlife habitat, navigation

Source: Central Valley Regional Water Quality Control Board 2011.

3.3.2 Groundwater Quality Objectives/Standards and Beneficial Uses

Beneficial uses of groundwater are designated in the Central Valley Regional Water Board Basin Plan. Unless otherwise designated, all groundwater in the Sacramento Valley is considered suitable, or at a minimum potentially suitable, for the following beneficial uses (Central Valley Regional Water Quality Control Board 2011).

- Municipal and domestic (MUN)
- Agricultural (AGR) – irrigation (IRR) and stock watering
- Industrial process (PROC)[7]
- Industrial service supply (IND)[8]
- Existing water quality

3.4 Regional Water Quality

Water in the Sacramento River Basin is generally considered to be relatively clean and acceptable for a variety of beneficial uses. Because most of the water in the Sacramento River and its major tributaries, such as the Feather and American Rivers, is derived from melting snow that enters the rivers by managed discharges of water from reservoirs, much of the Sacramento River and its large tributaries have low concentrations of dissolved minerals. Although water quality of the Sacramento River is good most of the year, seasonal events—such as agricultural runoff or runoff from historical mining operations—may affect this quality. Some water quality concerns related to these events are listed below (Sacramento River Watershed Program 2015).

- Erosion of stream channels and uplands, and increased turbidity and changes in sediment deposition patterns.
- Rising water temperatures from the loss of riparian canopy cover, streamflow diversions, and waste discharges.

[7] Process is industrial use that depends on water quality.
[8] Service supply is industrial use that is not dependent on water quality.

- Mercury and methylmercury levels from legacy mining sites that can be absorbed into and accumulate in the aquatic food chain.
- Aquatic toxicity from agricultural chemical use, including organophosphate pesticides in the Sacramento Valley.

3.4.1 List of Impaired Waters

Table 6 shows Section 303(d)-listed impairments for the Sacramento River based on the 2010 California Integrated Report (State Water Resources Control Board 2011).

Table 6. Section 303(d)-Listed Impairments for the Sacramento River

Reach	Section 303(d)-Listed Impairments	Source	TMDL Completion
Sacramento River (Knights Landing to the Delta)	Chlordane	Agriculture	Est. 2021
	DDT (dichlorodiphenyltrichloroethane)	Agriculture	Est. 2021
	Dieldrin	Agriculture	Est. 2021
	Mercury	Resource extraction	Est. 2012
	PCBs (polychlorinated biphenyls)	Unknown	Est. 2021
	Unknown toxicity	Unknown	Est. 2019

TMDL = total maximum daily load
Source: State Water Resources Control Board 2011

3.4.2 Construction General Permit Risk Level Assessment

Beneficial uses and status of impaired water bodies are used to determine permit requirements. A construction site risk level assessment was performed for the project Storm Water Pollution Prevention Plan (SWPPP), with a resultant **Risk Level 2 (**medium level**)**. The risk level was determined based on the procedure described in the Construction General Permit and based on two major elements: (1) project sediment risk (the relative amount of sediment that can be discharged, given the project and location details); and (2) receiving water risk (the risk that sediment discharges pose to the receiving waters). Project sediment risk is determined by multiplying the R, K, and LS factors from the Revised Universal Soil Loss Equation (RUSLE) to obtain an estimate of project-related bare ground soil loss expressed in tons/acre. Receiving water risk is based on whether a project drains to a sediment-sensitive water body. A *sediment-sensitive water body* is on the most recent Section 303d list for water bodies impaired for sediment; has a U.S. Environmental Protect Agency- (EPA-) approved total maximum daily load (TMDL) implementation plan for sediment; or has the beneficial uses of COLD, SPAWN, and MIGRATORY. More details on how the risk level was determined are provided in Attachment A.

Tables 7 and 8 summarize the sediment and receiving water risk factors and document the sources of information used to derive the factors.

Table 7. Summary of Sediment Risk

RUSLE Factor	Value	Method for Establishing Value
R	105	EPA website: http://cfpub.epa.gov/npdes/stormwater/LEW/lewCalculator.cfm.
K	0.14	Weighted average for surface layer of soil map units
LS	0.20	Field observations and LS Table from Sediment Risk Factor Worksheet in General Permit. Calculation assumes 1% slope (based on Natural Resources Conservation Service data) and 300-foot slope length.
Total predicted sediment loss (tons/acre)		2.94
Overall Sediment Risk Low sediment risk = < 15 tons/ acre Medium sediment risk = > 15 and < 75 tons/acre High sediment risk >= 75 tons/acre		☒ Low ☐ Medium ☐ High

RUSLE = Revised Universal Soil Loss Equation

Table 8. Summary of Receiving Water Risk

Receiving Water Name	303(d) Listed for Sediment-Related Pollutant[a]	TMDL for Sediment-Related Pollutant[a]	Beneficial Uses of COLD, SPAWN, and MIGRATORY[a]
Sacramento River	☐ Yes ☒ No	☐ Yes ☒ No	☒ Yes ☐ No
Overall receiving water risk			☐ Low ☒ High

[a] If "yes" is selected for any option, the receiving water risk is high.

3.4.3 Areas of Special Biological Significance

The proposed project is not within the vicinity of an Area of Special Biological Significance, as designated by the State Water Board (State Water Resources Control Board 2015).

Chapter 4 Environmental Consequences

4.1 Introduction

This chapter describes potential impacts on hydrology and water quality that could result from the proposed project. Construction activities may result in short-term impacts, such as the input of sediment loads and spills into water bodies. Long-term impacts include the increased potential for polluted runoff into water bodies. The chapter identifies the impacts of the project to the extent that they are reasonably foreseeable given the general level of project detail that is available at this time. Figure 2 shows the proposed bridge project and associated roadway alternatives, as well as the existing bridge and proposed removal of existing roadway approach structures.

4.2 Potential Impacts on Water Quality

The WQAR describes project-induced effects on water quality. For the purpose of this report, an impact is considered adverse if the proposed project would result in any of the following.

- Violate water quality standards or waste discharge requirements.
- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level.
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation onsite or offsite.
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding onsite or offsite.
- Create or contribute runoff water that would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff.
- Otherwise substantially degrade water quality.
- Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.

- Place within a 100-year flood hazard area structures that would impede or redirect flood flows.
- Expose people or structures to inundation by seiche or tsunami.

Short-term or temporary construction impacts on water quality have the potential to occur during grading, demolition, and construction related to the proposed replacement of the I Street Bridge. Potential sources of water pollution associated with the project include storm water runoff containing sediment from soil erosion, petroleum and wear products from motor vehicle operation, and accidental spills of hazardous materials during construction activities. Contaminants in runoff from the new bridge could include sediment, oils and grease, and heavy metals. Implementation of commonly used construction activity best management practices (BMPs) is anticipated to minimize any potential impacts on water quality to the maximum extent practicable. Post-project drainage would be designed so as not to be altered from pre-project drainage, and drainage would be directed to the storm drain system.

4.2.1 Anticipated Changes to the Physical/Chemical Characteristics of the Aquatic Environment

4.2.1.1 Substrate

In-channel construction and maintenance activities for the proposed bridge may alter the structure and composition of the river bed (or substrate). In-water construction work such as installation of temporary cofferdams and pile driving would disturb the bottom substrate over the stiff clay layer in the Sacramento River channel, which could remobilize sediments as well as contaminants adsorbed to the sediments. Non-soluble contaminants with a tendency to adsorb to sediments (as opposed to soluble contaminants, which have the tendency to be readily diluted in water) can accumulate in the substrate over time. Non-soluble contaminants that are known to be present in the Sacramento River include polychlorinated biphenyls (PCBs), mercury, pesticides and insecticides (i.e., dieldrin, chlorodane, DDT), and other unknown toxicities (State Water Resources Control Board 2011). The resuspension of contaminants found in bottom substrate can remobilize these contaminants and release them into the water column, degrading water quality. In addition, resuspended particulate material could be transported to other locations in the Sacramento River as a result of flow patterns and tidal currents, thus leading to potential degradation of water quality beyond the immediate project area.

4.2.1.2 Currents, Circulation, or Drainage Patterns

The proposed project may affect the water volume, depth, and flow rate in the Sacramento River, as well as surface drainage patterns during construction and operation of the project.

Proposed Bridge

The hydrologic study conducted for the project (MBK Engineers 2015) demonstrates that the proposed bridge would cause a negligible increase in the peak water surface elevation (WSE) of 0.02 foot immediately upstream and a negligible decrease in WSE from 0.06 to 0.07 foot for all three flood events evaluated (50-year, 100-year, and 200-year). Because changes in the water surface profile (water depth) would be negligible, the new bridge would cause virtually no impacts on the river hydraulics or floodplain of the Delta.

Roadway Modifications

During construction, utility improvements would involve relocation of some storm drains within Jibboom Street, Bercut Drive, C Street, and 2nd Street, which could temporarily affect the ability of water to drain in the surrounding area during a rain event. However, drainage would be re-routed to other active storm drain inlets during relocation activities. As is standard with all construction projects, the contractor would be required to install temporary BMPs to protect existing drainage inlets and storm drain systems and to control any runoff or erosion from the project site that may discharge into the surrounding waterways.

During operation, new impervious surface and changes in topography could alter surface runoff drainage patterns and river flows. However, project drainage has been considered in the design. As described in Section 1.1.3.4, the proposed roadway drainage would be conveyed to the existing storm drain system installed within Railyards Boulevard and C Street. Railyards Boulevard currently drains storm water to the east along the roadway and then into a retention basin south of Railyards Boulevard. C Street drains storm water west along the roadway and then ultimately south beyond the project limits. Drainage from the bridge itself would be directed to drains located on the bridge and routed to the abutment, where it would enter the storm drainage system.

4.2.1.3 Suspended Particulates (Turbidity)

During construction, potential short-term increases in turbidity would result from soil erosion and suspended solids being introduced into the Sacramento River, from both in-water and land construction activities. This could violate water quality standards or WDRs related to turbidity and have the potential to result in physiological, behavioral, and habitat effects on aquatic life (ICF International 2015a).

Proposed Bridge

In-water construction activities in the Sacramento River would directly disturb sediment along the river bed and result in a temporary increase in turbidity in the immediate project area and potentially downstream. The potential for disturbance of riverbed sediments and associated increases in sedimentation and turbidity in the Sacramento River are anticipated to be greatest during extraction of temporary trestles and cofferdams installed during in-water work for bridge construction. These activities would result in greater disturbance to riverbed sediments than would occur during pile driving for piers and the bridge fender system; these piles would be driven only and not extracted (ICF International 2015a).

Dewatering may be needed for (1) removal of water from within the CIDH piles after they complete pile driving and prior to pouring the concrete inside the CIDH pile cage; and/or (2) removal of the water that is displaced as the concrete is poured.

The first instance involves partial or complete dewatering without any new contaminants. The discharge of turbid water would be prevented by filtering the discharge first using a filter bag, diverting the water to a settling tank or infiltration area, and/or treating the water in a manner to ensure compliance with water quality requirements prior to discharging water back to the Sacramento River or any canal, ditch, wetland, or other aquatic habitat. This type of dewatering would occur if the casings were dewatered partially before pouring concrete or if cofferdams are used and dewatering is needed to rescue fish. If casings remain on for at least 1–2 days after the work is completed, sediments would settle in the casings before the casings are pulled.

The second instance requires preventing the discharge of concrete to Sacramento River by diverting and properly disposing of water displaced from within CIDH piles as concrete is being poured. The water likely would contain uncured concrete. A Low-Threat Dewatering Permit would not be needed if the water within the encasements that comes in contact with the cement is pumped out, placed in a container, and hauled to a hazardous waste facility where it would be properly treated and disposed. However, if it is discharged to the Sacramento River or nearby storm drains, monitoring and treatment of constituents associated with concrete (e.g., pH, hardness) would need to be conducted in compliance with the conditions of the Low-Threat Dewatering Permit prior to discharge. If the water is discharged to land, such as to temporary infiltration basins, the project would need to obtain a General Dewatering Permit for Land Discharges. For example, water could be treated and neutralized within Baker Tanks then allowed to infiltrate in basins or used for dust control.

Roadway Modifications

Construction activities occurring on land adjacent to the river channel could cause erosion of sediments and contribute to short-term increases in turbidity in the river. Land-disturbing activities (e.g., vegetation clearing, excavation, and grading) could result in erosion and subsequent soil deposition to the river, which would increase river turbidity. Table 9 lists the acreages of each land cover type in the biological study area[9] (as described in the NES for the project) that would be permanently or temporarily affected by the proposed project, and Figure 5 shows these areas in a map series for reference. As shown in the table, the proposed project with West Sacramento Residential Access Alternative 1 would result in slightly more developed/ graded land disturbance than the proposed project with West Sacramento Residential Access Alternative 2. There are no impact acreage differences as a result of the City of Sacramento roadway design alternatives.

Table 9. Permanent and Temporary Impacts on Land Cover Types in the Biological Study Area

Land Cover Type	Proposed Project with West Sacramento Residential Access Alternative 1[a]		Proposed Project with West Sacramento Residential Access Alternative 2[a]	
	Permanent and Indirect Impact Area (acres)	Temporary Impact Area (acres)	Permanent and Indirect Impact Area (acres)	Temporary Impact Area (acres)
Cottonwood riparian forest[b]	2.49	1.93	1.45	1.66
Riparian forest/shrub wetland[b]	0.07	0.11	0	0
Tidal perennial drainage[b]	0.53	3.60	0.53	3.60
Ruderal woodland	2.01	1.70	2.01	1.70
Landscaped	0.63	0.70	0.54	0.63
Developed/graded	8.18	6.55	7.70	6.36
Total	13.91	14.59	12.23	13.95

[a] There are no impact acreage differences as a result of the City of Sacramento roadway design alternatives.
[b] These are natural communities of special concern.
Source: ICF International 2015a.

Construction of the proposed project would disturb more than 1 acre of land. Because the project is on and adjacent to the Sacramento River, Construction General Permit SWPPP erosion and sediment control BMPs would be implemented to prevent or minimize sediment and suspended solids from entering the river.

During operation, long-term water quality impacts are attributable to changes in storm water drainage and/or loss of riparian vegetation. The proposed project would result in a permanent loss of 1.88 acres of levee slope vegetation (1.13 acres in West Sacramento and 0.75 acre in

[9] The biological study area includes all areas of proposed permanent and temporary impacts, as well as the area under I-5 and adjacent to the proposed removal of roadway approach structures in the City of Sacramento and parcels adjacent to some of the proposed road improvements in the City of West Sacramento.

Sacramento) for RSP and permanent structures. Vegetation along slopes can help reduce the potential for erosion during rain events.

The proposed project would result in added impervious surface that would have the potential to increase runoff volume in the Sacramento River. Increases in impervious surfaces change the storm hydrograph by increasing flow velocity and the peak and quantity of storm runoff due to reduced natural infiltration (groundwater recharge) and uptake from native soils and vegetation. Further, if periodic maintenance of the bridge were to require in-water work, there would be the potential for sediment disturbance and turbidity. The project design will incorporate Construction General Permit SWPPP post-construction measures, site design measures, LID measures, and other permanent erosion control elements found in Caltrans' MS4 program guidance documents, Sacramento Stormwater Quality Partnership's SQIP, and the City of West Sacramento's SWMP, to ensure that storm water runoff does not cause soil erosion. Implementation of these measures would reduce or avoid permanent impacts on water quality.

4.2.1.4 Oil, Grease, and Chemical Pollutants

The use of heavy construction equipment or construction-related materials or post-construction roadway operations can introduce pollutants of concern or toxic chemicals to the project site, which has the potential to violate water quality standards or WDRs. In addition, some of these pollutants can accumulate in stream sediments with lethal and sublethal consequences for fish and other aquatic species, particularly during "first-flush" rain events (ICF International 2015a).

Proposed Bridge

Construction chemicals may be accidentally spilled into watercourses during in-water work. A typical construction site uses many chemicals or compounds, including gasoline, oils, grease, paint, solvents, lubricants, and other petroleum products. Many petroleum products contain a variety of toxic compounds and impurities; they tend to form oily films on the water surface, altering oxygen diffusion rates. Concrete, soap, trash, and sanitary wastes are other common sources of potentially harmful materials at construction sites. Washwater from equipment and tools and other waste accidently spilled on the construction site can lead to introduction of pollutants into surface waters or seepage into groundwater. The impact of toxic construction-related materials on water quality depends on the duration and time of activities. Construction occurring in the dry season is less likely to cause soil and channel erosion or runoff of toxic chemicals into a stream. However, low summer flows are less able to dilute pollutants that do enter the watercourse.

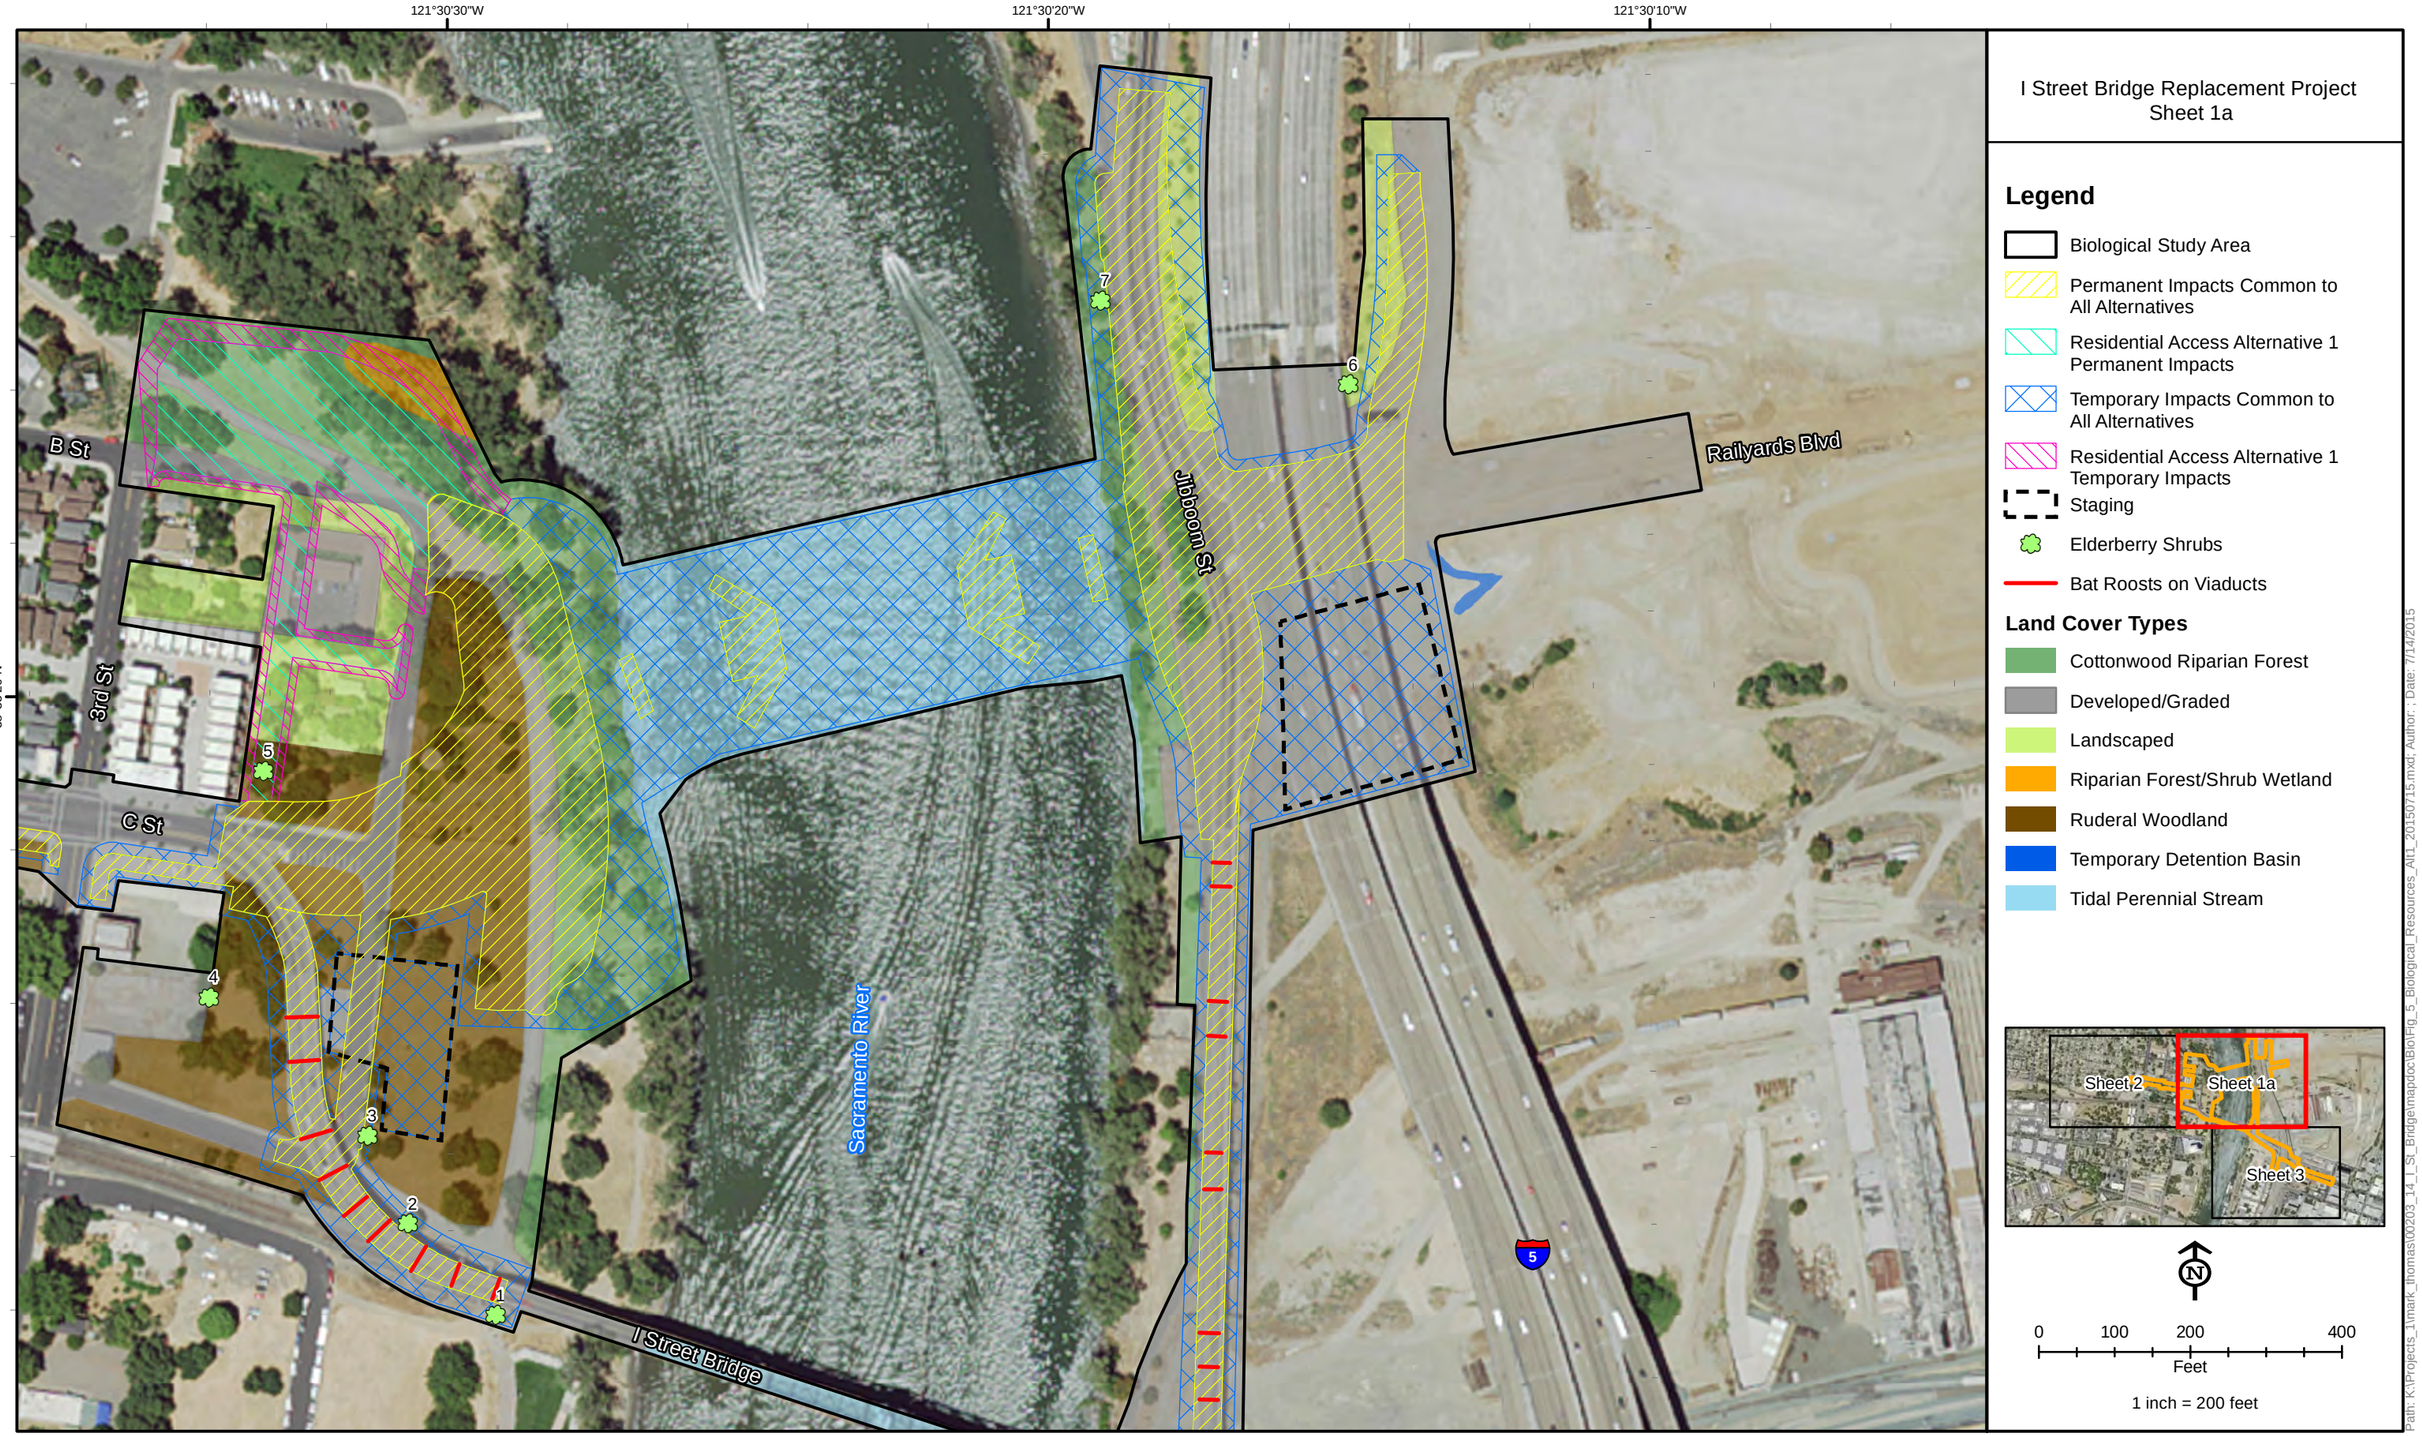

Figure 5
Impacts on Landcover Types and Sensitive Biological Resources in the Biological Study Area

Roadway Modifications

Heavy metals, oil, grease, and polycyclic aromatic hydrocarbons are common pollutants in road runoff, and roadside landscaping can introduce pesticides and fertilizers. These pollutants are typically washed off the roadway surfaces by rainfall and enter storm water runoff. Urban runoff from vehicles on bridges can be discharged into streams during rain events, in vehicle accidents, and through normal wear and tear. Runoff in significant quantities occurs only during heavy storms that in turn cause these pollutants to be greatly diluted. These storms cause some high flows in the drainage systems, which dilute the pollutants as they are carried from the source.

The construction contractor would be required to regularly inspect and maintain the BMPs to ensure that they are in good working order, as required in the Construction General Permit SWPPP. The contractor would implement appropriate hazardous material management practices, spill prevention, and other good housekeeping measures to reduce the potential for chemical spills or releases of contaminants, including any non-storm water discharge to drainage channels. Implementation of these measures would minimize the potential for surface water and groundwater contamination.

Overall, post-construction bridge and roadway runoff is not expected to adversely affect water quality in the Sacramento River, as runoff would be collected and diverted via ducts and culverts to a storm drain system rather than to the river itself.

4.2.1.5 Temperature, Oxygen Depletion, and Other Parameters

Changes in temperature, dissolved oxygen levels, or other parameters of a water body could violate water quality standards or WDRs. These changes could cause algal blooms and adversely affect sensitive aquatic life. Low dissolved oxygen levels can be the result of algal blooms.

Proposed Bridge

Temperature can be affected if water of a different temperature is discharged directly into waters or if water depths are substantially changed in a river, resulting in seasonal changes in air temperature and solar radiation with a greater (with lower water levels) or lesser (with greater water levels) influence on river water temperatures. Vegetative canopy cover (overhanging vegetation) maintains cooler temperatures in the underlying water. Removal of streamside vegetation may affect water temperatures. In addition, new overwater structures, such as the new bridge, could alter underwater light conditions and resulting water temperatures. Because of the height of the new bridge over the water, ambient light levels generally would be expected to penetrate into the water, thereby minimizing the effect of bridge shading on aquatic habitats in the Sacramento River.

Low river flows (or stagnant water) and algal blooms can affect dissolved oxygen levels. Neither of these conditions are expected to occur as a result of the project. In addition, the Sacramento River is not impaired for dissolved oxygen or temperature; therefore, these parameters are not likely to result in levels detrimental to aquatic life as a result of the project.

Remobilization of nutrients found in bed sediments during construction could release increased nutrients into the water column, causing an algal bloom. However, remobilization of these nutrients would be temporary and would not be in quantities large enough to cause algal blooms in the river due to its continual flow.

Roadway Modifications

Landscaping activities for roadside vegetation could include the use of pesticides, herbicides and fertilizers. Landscaping runoff can be discharged in nearby storm drains or via runoff directly into the Sacramento River. As shown in Table 8, the Sacramento River is impaired for pesticides (chlordane, DDT, and dieldrin). In addition, fertilizers can be a source of nutrients that could cause algal blooms. Pesticides and fertilizers, if used on riparian or roadside vegetation, would be properly applied according to the regulations of the California Department of Pesticide Regulation to ensure that waterways are not exposed.

4.2.1.6 Flood Control Functions

As previously described in Section 3.2.3, under "Flood Plains," the project site is located within the 100-year Flood Zone AE and Flood Zone X (unshaded) or C, which is an area of minimal flood hazard. Bridge structures within a 100-year flood hazard area could impede or redirect flood flows. In addition, alteration of drainage patterns of the site or area, including through the alteration of the course of a stream or river, could result in flooding onsite or offsite.

Proposed Bridge

According to the Preliminary Hydraulic Impact Analysis for the project (MBK Engineers 2015), the new bridge would be designed according to the following criteria defined in the California Department of Water Resources' (DWR's) FloodSafe California Urban Levee Design Criteria.

- Levees protecting urban areas are assumed to have a minimum crown elevation equal to the 1-in-200 Azimuth-over-Elevation Positioning (AEP) WSE plus 3 feet.
- Non-urban state/federal project levees are assumed to meet the authorized minimum elevation.
- Levees act as weirs and do not breach if overtopped.

The bridge design was analyzed for impacts from the 200-year flood (Q200), 100-year flood (Q100) and the 50-year flood (Q50). It was found that the proposed bridge results in a negligible increase in the peak WSE of 0.02 foot immediately upstream of the Project for all three of the flood events evaluated. Downstream of the project, there is a 0.06- to 0.07-foot reduction in the peak WSE. The reduction in WSE downstream of the project is due to a reduction in the peak flow in the Sacramento River downstream of the American River that is caused by the small increase in the WSE upstream of the project. The increase in WSE upstream of the project translates to an increase at the American River, thereby reducing the percentage of American River flow that goes downstream in the Sacramento River and increasing the percentage that flows upstream to the Sacramento Weir. As with the effect on the WSE, the effect on the flows is negligible.

In addition to DWR's FloodSafe California Urban Levee Design Criteria, the new bridge would be designed according to hydraulic design criteria established in the Caltrans Local Assistance Procedures Manual. The criteria dictate that the facility be capable of conveying the base or Q100 and passing the Q50 "without causing objectionable backwater, excessive flow velocities or encroaching on through traffic lanes." The same criteria also recommend a minimum freeboard clearance of 2 feet above the 50-year floodwater surface elevation (WSE50) to provide clearance for drift. Due to the potential for significant drift during high flows in this channel, increasing the freeboard clearance to 3 feet above the WSE50 is reasonable.

Roadway Modifications

Roadway improvements are not expected to increase flood risk because (1) new impervious area is expected to be minimal; (2) drainage system improvements would be designed to accommodate storm drain infrastructure capacities and prevent ponding; and (3) the roadways would be at-grade and therefore would not obstruct or redirect flood flows.

4.2.1.7 Storm, Wave, and Erosion Buffers

The proposed project is not located within a tidally-influenced area nor a wetland. It is located approximately 80 miles inland from the coast and therefore would not be vulnerable to large storm waves that typically threaten coastline areas. The proposed project would not change the potential for storm waves to affect upland areas or existing erosion buffers (i.e., wetlands).

4.2.1.8 Erosion and Accretion Patterns

Proposed Bridge

Accretion refers to the gradual accumulation of sediments along channel banks via the deposit, by water, of solid material—whether mud, sand, or other sediments due to factors such as channel geomorphology and flow obstructions. Because the proposed project is located in an area primarily composed of dense and compact soil that is not easily erodible, accretion is not expected to occur.

Sedimentation is the tendency for particles in suspension to settle out of the fluid in which they are entrained and to come to rest against a barrier. Larger particles like gravel and sand settle out more rapidly than fine particles like silt and clay. The Preliminary Hydraulic Impact Analysis for the project (MBK Engineers 2015) evaluated the potential for debris loading on the piers. In accordance with guidance provided by the CVFPB for hydraulic analyses, the debris loading was assumed to be 2 feet in depth for a width twice the width of the pier. Potential impacts of the proposed project on erosion patterns also are discussed in Section 4.2.1.3, Suspended Particulates (Turbidity).

Roadway Modifications

Land disturbance activities, such as grading and excavation during construction, would loosen the soil and could remove the protective cover of vegetation, thereby reducing the natural soil resistance to rainfall impact erosion.

As noted above, implementation of erosion and sediment control BMPs during construction would prevent or minimize sediment and suspended solids from entering the river. The project design also will include permanent erosion control elements to ensure that storm water runoff does not cause soil erosion, thus reducing or avoiding permanent impacts on water quality.

4.2.1.9 Aquifer Recharge/Groundwater

Proposed Bridge

Construction activities related to installing bridge columns may require groundwater dewatering should groundwater be encountered below the riverbed and along the bridge landings. The piles would be driven to a depth of approximately 70 feet below the original ground elevation. As previously mentioned, a Low-Threat Dewatering Permit would not be needed if the water within the encasements that comes in contact with the cement is pumped out, placed in a container, and hauled to a hazardous waste facility where it would be properly treated and disposed. However, if it is discharged to the Sacramento River or nearby storm drains, monitoring and treatment of

constituents associated with concrete (e.g., pH, hardness) would need to be conducted in compliance with the conditions of the Low-Threat Dewatering Permit prior to discharge.

Roadway Modifications

As previously described, groundwater was found at a depth of approximately 15 to 25 feet below the ground surface. Roadway improvements and utility installation and trenching would require excavation to depths of only a few feet.

Should the proposed project require groundwater dewatering during construction activities, groundwater resources would be minimally affected because the required excavations would intersect only the shallow water table on a temporary basis during the construction period. Although this could result in short-term, localized alterations in groundwater levels near the surface in the immediate vicinity of the construction site, the reduction would not cause a widespread, regional drawdown and likely would be quickly recharged due to saturated groundwater characteristics. Changes to groundwater occurrence and levels due to project construction and operation, if groundwater levels are affected at all, would not detrimentally affect regional groundwater production or change the existing water quality. Groundwater dewatering would not be necessary for project operation and maintenance activities.

As previously described, the majority of water supply comes from surface water sources, not groundwater resources. Water used during project construction may be trucked in or extracted from nearby fire hydrants, and the use would be temporary. In addition, the project would not need continual water supplies for operation and maintenance activities. Therefore, groundwater levels would not be affected from water used during project construction or operation.

4.2.1.10 Baseflow

Baseflow is the portion of streamflow that comes from groundwater seepage during a drought or after an extended dry period with little rain to replenish the stream. During periods of low surface flow (dry season), the shallow groundwater table can play a large role in providing baseflows to the Sacramento River. As previously described, the proposed project would not affect groundwater levels on a long-term basis, if at all, and therefore would not affect the baseflow levels in the Sacramento River during the dry season.

4.2.2 Anticipated Changes to the Biological Characteristics of the Aquatic Environment

The following section addresses biological resources that may be affected by the proposed project and is based on the project NES (ICF International 2015a).

4.2.2.1 Special Aquatic Sites

Special aquatic sites, referred to as *environmentally sensitive areas*, would be protected with barrier fencing or stakes during construction, and would be identified on the construction plans (ICF International 2015a). Please see the project NES (ICF International 2015a) for more information regarding potential impacts of the project on environmentally sensitive areas.

4.2.2.2 Habitat for Fish and Other Aquatic Organisms

The proposed project would result in the temporary and permanent loss of aquatic habitat area and volume, including foraging and rearing habitat for juvenile winter-run Chinook salmon (ICF International 2015a).

Installation of sheet pile cofferdams to isolate the in-water construction areas for piers 2 and 5 from the water column during pier construction would result in the temporary loss of aquatic habitat (substrate and water column) equal to the enclosed area and volume of the in-water cofferdams. The proposed dimensions of each cofferdam are 25 feet by 80 feet, or 2,000 square feet. Together, the two cofferdams would result in a temporary loss of 4,000 square feet (0.09 acre) of substrate habitat and up to 73,640 cubic feet of water column habitat below the OHWM (based on a water surface elevation of +20 feet).

In addition, installation of the new bridge piers (piers 2–5) and piles for the new bridge fender system would result in the permanent loss of aquatic habitat (substrate and water column) equal to the cumulative area (substrate) and volume (water column) of the in-water piers and bridge fender piles. Similarly, placement of rock revetment (rip-rap) around the new bridge piers and on the waterside slope of the existing levees below the OHWM would result in the permanent loss of natural substrate habitat equal to the net increase in area of rock revetment.

Installation of these features may result in direct and indirect effects by inhibiting establishment of riparian vegetation; inhibiting recruitment and retention of sediment and woody debris; and eliminating shallow, low-velocity river margins preferred by juvenile fish.

Compensation for impacts on critical habitat, as described in the project NES (ICF International 2015a), would offset the effects of permanent impacts on the substrate and water column resulting from construction of the new bridge piers.

Avoidance and minimization measures described in the project NES (ICF International 2015a) would further avoid or minimize the potential for construction-related effects on aquatic habitat in the project area.

4.2.2.3 Fish Passage (Beneficial Uses)

Fish passage may be limited during in-water construction work, but obstructions would be temporary. All in-water construction work and pile driving (in-water and shore-based within 250 feet of the Sacramento River), installation of cofferdams, removal of temporary sheet piles, and placement of rock revetment would be conducted during the time periods allowed by the regulatory agencies to avoid or minimize causing disturbance and injury to, or mortality of, special-status fish species in the affected reaches of the Sacramento River. In addition, in-water work would be conducted during daylight hours only to provide fish in the affected reaches of the Sacramento River with an extended quiet period during nighttime hours for feeding and unobstructed passage. (ICF International 2015a).

Avoidance and minimization measures described in the project NES (ICF International 2015a) would further avoid or minimize the potential for construction-related effects on fish passage in the project area.

4.2.2.4 Wildlife Habitat

Wildlife habitat would be protected from temporary impacts with avoidance measures (i.e., seasonal restrictions) and fencing around the project area to prevent the presence of wildlife in the construction site.

Avoidance and minimization measures described in the project NES (ICF International 2015a) would further avoid or minimize the potential for construction-related effects on wildlife habitat in the project area.

4.2.2.5 Wildlife Passage (Beneficial Uses)

Wildlife passage may be temporarily limited due to fencing around the project site to prevent the presence of wildlife in the construction site, but passage would not be inhibited post-project. In addition, removal or replacement of riparian areas may affect trees that would support birds, such as Swainson’s hawk.

Avoidance and minimization measures described in the project NES (ICF International 2015a) would further avoid or minimize the potential for construction-related effects on wildlife passage in the project area.

4.2.2.6 Endangered or Threatened Species

The project could result in the potential loss or disturbance of nesting species state listed as threatened. Special-status species potentially affected by the project include the state-listed

Swainson's hawk (*Buteo swainsoni*) and the CDFW fully protected white-tailed kite (*Elanus leucurus*). Green sturgeon (*Acipenser medirostris*) was classified as a Class 1 Species of Special Concern by CDFW in 1995 (Moyle et al. 1995). Class 1 Species of Special Concern are those that conform to the State definitions of threatened or endangered and could qualify for addition to the official list. Elderberry shrubs that represent habitat for the federally threatened valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) could be affected by the project, which could result in injury to or mortality of beetles. The project also could affect habitat for the delta smelt (federally listed as threatened) based on temporary effects on water quality (increased turbidity and suspended sediment), rearing and movement habitat (noise and shade), and channel substrates (cofferdams and temporary trestles); temporary and permanent effects on riparian and shaded riverine aquatic cover habitat (vegetation removal, bridge and bike path construction); and permanent effects on aquatic habitat (construction of bridge piers, shade, and placement of RSP) in the Sacramento River.

Avoidance and minimization measures described in the project NES (ICF International 2015a) would further avoid or minimize the potential for construction-related effects on endangered or threatened species in the project area.

4.2.2.7 Invasive Species

During construction, the operation of barges and other in-water equipment originating from outside the project area could result in the introduction and spread of aquatic invasive species, including the Asian overbite clam (*Corbula amurensis*), quagga mussel (*Dreissena bugensis*), zebra mussel (*Dreissena polymorpha*), hydrilla (*Hydrilla verticillata*), and Brazilian elodea (*Egeria densa*) (California Department of Fish and Game 2008).

The proposed project has the potential to create additional disturbed areas for a temporary period and to introduce and spread invasive plant species to uninfected areas within and adjacent to the project area. This would be of particular concern for natural communities of special concern, where non-native invasive plants could outcompete and replace native vegetation. No plant species designated as federal noxious weeds have been identified in the project area (ICF International 2015a).

Avoidance and minimization measures described in the project NES (ICF International 2015a) would avoid or minimize the potential for project-related effects due to the introduction and spread of invasive aquatic and plant species in the project area.

4.2.3 Anticipated Changes to the Human Use Characteristics of the Aquatic Environment

This section addresses the potential effects of the proposed project on human use characteristics, including beneficial uses of the Sacramento River.

4.2.3.1 Existing and Potential Water Supplies; Water Conservation

The project would not require the use of water supplies and therefore would not affect beneficial uses of the Sacramento River related to municipal and domestic, industrial process and service, and agricultural water supplies.

4.2.3.2 Recreational or Commercial Fisheries

The project would affect only a small section along the Sacramento River, would not affect fishery supplies, and therefore would not affect recreational or commercial fisheries. Consequently, the proposed project would not affect beneficial uses of the Sacramento River related to non-contact water recreation (i.e., fishing).

4.2.3.3 Other Water-Related Recreation

Boating and other water recreation activities are common in the Sacramento River. The new bridge would be designed so as not to affect the ability of boaters, water skiers, and swimmers to use the river. Therefore, the proposed project would not affect the beneficial use of the Sacramento River related to water contact recreation.

4.2.3.4 Aesthetics of the Aquatic Ecosystem

Please see the project Visual Impact Assessment (ICF International 2015a) for a more detailed discussion of the visual and aesthetic changes of the proposed project. The new bridge would change the aesthetics of the project area, including the aesthetics of the aquatic ecosystem. The largest visual change would be the introduction of a new bridge across the Sacramento River. The new bridge would be visible from the river's edge at public access points like the Broderick Boat Ramp. The new bridge would also be visible by those standing at the water's edge, boaters on the river, rail passengers crossing the existing I Street Bridge, and pedestrians on the water intake's public promenade. In addition, new RSP added to prevent erosion near the bridge would be visible along the shoreline. Thee RSP would weather and darken, and would appear similar to other RSP installations along the river. The aesthetic change would be localized and the proposed project would have a minimal impact on the aesthetics of the aquatic system.

4.2.3.5 Parks, National and Historic Monuments, National Seashores, Wild and Scenic Rivers, and Wilderness Areas

The Sacramento River is not a designated Wild and Scenic River, nor is it designated as a national or historic monument or located in a wilderness area. No national and historic monuments, national seashores, or wilderness areas are located in the project area. There are parks along each bank of the river near the proposed project: Sacramento River Parkway in Sacramento, and River Walk Park and Broderick Boat Ramp in West Sacramento. Access to the Broderick Boat Ramp by land or river would not change during project construction. Replacement of the bridge would temporarily affect the Sacramento River Parkway and the Class I trail that runs along the river bank in the parkway. A trail detour would be required in order to construct the new bridge landing on the Sacramento bank of the river. Also, access to a path that connects River Walk Park to undeveloped land north of the existing I Street Bridge would be temporarily affected. Because these impacts would be temporary, the proposed project would result in a limited impact on resources associated with special designations.

4.2.3.6 Energy Consumption or Generation

No hydropower facilities are located in the project area, and construction and operation of the proposed project would not require high consumption of energy. Therefore, the proposed project would not affect energy consumption or generation capabilities.

4.2.3.7 Navigation

As described in Section 1.1.3, Project Alternatives, the Sacramento River is considered to be a navigable waterway of the United States. Under the provisions of the General Bridge Act of 1946, as amended, the proposed location and plans for bridges over navigable waters of the United States must be approved by the U.S. Coast Guard, prior to commencing construction. In order to comply with the U.S. Coast Guard requirement to maintain navigation along the river, the new bridge would be a movable bridge. The bridge design has been developed to accommodate river boat traffic and navigation under the existing I Street Bridge and the proposed bridge and therefore would not impede riverine navigation.

4.2.4 Short-Term Impacts during Construction

4.2.4.1 Physical/Chemical Characteristics of the Aquatic Environment

Short-term or temporary construction impacts on water quality could occur during grading, demolition, and other construction activities related to the proposed project. Construction activities would comply with a variety of restrictions and agency requirements, such as permits

from the Central Valley Regional Water Quality Control Board, USACE, and CDFW. Implementation of the SWPPP, and the performance standards of Caltrans and Sacramento and Yolo County storm water ordinances would minimize the potential for construction-related surface water pollution—and would ensure that water quality in the Sacramento River would not be compromised by erosion and sedimentation during construction. Short-term impacts on physical/chemical characteristics of the aquatic environment during construction are described further in Section 4.2.1.

4.2.4.2 Biological Characteristics of the Aquatic Environment

Please see the project NES (ICF International 2015a) for information regarding short-term impacts of the project on biological characteristics of the aquatic environment. Avoidance and minimization measures described in the project NES would avoid or minimize the potential for construction-related effects on biological resources in the project area.

4.2.4.3 Human Use Characteristics of the Aquatic Environment

As described in Section 4.2.3, the proposed project would not affect human uses, including designated beneficial uses, of the Sacramento River in the short term during construction of the new bridge.

4.2.5 Long-Term Impacts during Operation and Maintenance

4.2.5.1 Physical/Chemical Characteristics of the Aquatic Environment

Following completion of the proposed project, there is potential for long-term water quality impacts from operation and maintenance activities, such as bridge maintenance, inspections, and repairs. Long-term impacts include alterations in drainage patterns on the bridge, bridge approaches, and roadways and alterations in polluted surface runoff.

The proposed project would adhere to the Statewide Caltrans Stormwater Permit requirements. Compliance with these requirements by implementing post-construction BMPs will ensure that storm water pollution during operation and maintenance of the project would be minimal. Standard facilities used to handle storm water onsite would be an array of structural elements or facilities that would serve to manage, direct, and convey the storm water. Project design measures, such as LID measures, are a means of complying with municipal storm water permits. Implementation of post-construction BMPs would minimize impacts on water quality during long-term operations at the site. Long-term impacts on physical/chemical characteristics of the aquatic environment are described further in Section 4.2.1.

4.2.5.2 Biological Characteristics of the Aquatic Environment

Please see the project NES (ICF International 2015a) for information regarding long-term impacts of the project on biological communities. Avoidance and minimization measures described in the project NES would further avoid or minimize the potential for construction-related effects on aquatic habitat in the project area.

4.2.5.3 Human Use Characteristics of the Aquatic Environment

As described in Section 4.2.3, the proposed project would not affect human use characteristics, including designated beneficial uses, of the Sacramento River in the long term during bridge operation and maintenance.

4.3 Impact Assessment Methodology

Potential impacts resulting from implementing the proposed project were analyzed by comparing existing conditions, as described in the Environmental Setting, to conditions during construction and operation and maintenance of the project. The qualitative analysis assesses the direct and indirect, short- and long-term impacts related to surface hydrology, flood hazards, groundwater recharge, and surface water and groundwater quality as described below.

- **Surface Water Hydrology:** The surface water hydrology impact analysis considered potential changes in the physical characteristics of water bodies, impervious surfaces, and drainage patterns in the project area as a result of project implementation.
- **Flood Hazards:** The impact analysis for flood risk was conducted using FEMA NFIP maps to determine whether the project area overlaps with existing designated 100-year floodplains.
- **Groundwater Recharge:** Impacts on groundwater recharge were assessed by comparing existing sources of recharge versus recharge capabilities following project implementation. Recharge is determined by the ability of water to infiltrate into the soil.
- **Surface Water and Groundwater Quality:** Impacts of the proposed project on surface water and groundwater quality were analyzed using existing information on existing water quality conditions (i.e., 303[d]-listed water bodies), and potential existing sources of water contaminants generated by bridge construction, operation, and maintenance activities. The analysis also considered the potential for water quality objectives to be exceeded, beneficial uses to be compromised, and further degradation of impaired waters as a result of the proposed project.

4.4 Alternative-Specific Impact Analysis

The proposed project under consideration includes one bridge alignment for the new bridge over the Sacramento River and two roadway design alternatives for portions of the roadway design in both Sacramento and West Sacramento. The storm water drainage management plan, structure demolition and roadway modification, and construction storage and staging elements apply to the proposed project and roadway design alternatives together. These elements are considered the most pertinent when analyzing project impacts on hydrology and water quality. Therefore, the proposed project with the roadway design alternatives is considered together as the Build Alternative in this analysis and compared to the No Build Alternative. Where there are differences between the roadway design alternatives, they are identified.

4.4.1 Build Alternatives

The project proposes to construct a new bridge and remove the approach structures at the existing bridge. The analysis in this report addresses potential impacts from the proposed project (new bridge and removal of the existing bridge) with alternatives for roadway design, as described in Section 1.1.3, Project Alternatives. There are two roadway project design alternatives for the Railyards Boulevard/Jibboom Street/Bercut Drive intersection in the City of Sacramento, both of which address different designs for intersections. There are two roadway project design alternatives for residential property access in West Sacramento, both of which address different designs for access to residential properties.

- City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection
  - Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive
  - Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive
- City of West Sacramento Residential Access
  - Alternative 1—C Street Connection to B Street
  - Alternative 2—C Street Connection to 3rd Street

Both roadway design alternatives in the City of Sacramento would result in the same impact on hydrology and water quality resources and therefore are not discussed separately. However, because the City of West Sacramento alternatives have different footprints for residential access, some of the differences in impacts are described separately in the analysis (in Section 4.2 under the “Roadway Modifications” heading) as the (1) proposed project with West Sacramento Residential Access Alternative 1; and the (2) proposed project with West Sacramento Residential Access Alternative 2.

4.4.2 No Build Alternative

Under the No Build Alternative, no bridge would be built and the existing I Street Bridge would continue to be a source of transportation across the Sacramento River between the City of Sacramento and the City of West Sacramento. Because this alternative does not alter existing conditions, there would be no associated impacts on water quality. However, this alternative does not meet the purpose and need of the proposed project.

4.5 Cumulative Impacts

This cumulative analysis examines the effects of the proposed project in combination with other current projects, probable future projects, and projected future growth along the Sacramento River on either the Sacramento or West Sacramento side. The geographic context for the analysis of cumulative impacts associated with surface water hydrology and water quality is the Lower Sacramento Valley Watershed. The context for groundwater hydrology is the Sacramento Valley Groundwater Basin. The context for cumulative hydrology and water quality impacts is geographic and is a function of whether impacts could affect surface water features/watersheds, municipal storm drainage systems of the Cities of Sacramento and West Sacramento, or groundwater in these areas—each of which has its own physical boundary. This analysis accounts for anticipated cumulative growth within the potentially affected geographic area as represented by full implementation of the county and city General Plans. Current and future planned development are identified in the Sacramento Railyards Specific Plan (east of the proposed project) in the City of Sacramento, and in the Washington Specific Plan and Bridge District Specific Plan areas (west of the proposed project) in the City of West Sacramento, as described in Section 2.3, Regional and Local Requirements.

4.5.1 Contribution to Significant Cumulative Water Quality Impacts

Development of the project combined with other past and future development within the potentially affected geographic area could degrade storm water quality through an increase in impervious surface area and increase in contaminated runoff, which ultimately could violate water quality standards, affect beneficial uses, and/or further impair 303(d)-listed waters within the Lower Sacramento Valley Watershed and the Sacramento Valley Groundwater Basin. Water quality of storm water runoff varies with surrounding land uses, topography, and amount of impervious cover—as well as with the intensity (energy) and frequency of irrigation or rainfall. During construction, runoff may contain sediments and other construction materials and wastes (e.g., concrete debris) resulting from activities such as site clearing and grubbing, demolition and removal of existing structures and pavement, cut-and-fill activities, grading and excavation,

paving, building construction, tree removal, and landscaping. During operation, runoff may contain oil, grease, and metals accumulated in the streets and driveways, in addition to pesticides, herbicides, particulate matter, nutrients, animal waste, and other oxygen-demanding substances from landscaped areas. The highest pollutant concentrations are generally in storm water runoff generated at the beginning of the wet season and during the first flush, where approximately 80% of total accumulated pollutants are washed off surfaces with the first 0.5 inch of rainfall, with street surfaces as the primary source of pollutants in urban areas.

Planned development could affect water quality if the land use changes, the intensity of land use changes, and/or drainage conditions are altered to facilitate the introduction of pollutants to surface water or groundwater resources. Changes in land use would alter the associated type and amount of pollutants in storm water runoff (e.g., higher fecal coliform concentrations in runoff from residential lands compared to commercial lands). Increased intensity of land use would increase the potential pollutant loads. Alterations in drainage patterns could increase pollutant loads by increasing the amount of storm water runoff transporting pollutants, could cause or contribute to erosion if the rate of runoff is increased, and could expose vulnerable areas to infiltration or runoff.

Construction of the proposed project as well as construction of other planned projects in the vicinity would result in surface disturbance through grading, trenching, and compaction associated with typical development activities. Existing vegetation would be removed, thereby increasing the potential for erosion. Consistent with municipal storm water programs for Sacramento, West Sacramento, and Caltrans, project-specific SWPPPs would include implementation of construction BMPs. In addition, other necessary site-specific permits (i.e., Water Quality Certification, Low-Threat Dewatering Permit, Streambed Alteration Agreement, Section 404 Permit) would be obtained for this and other planned projects; and associated measures would be implemented to sufficiently reduce potential surface water quality impacts during construction, preventing cumulative impacts. Therefore, the proposed project would not contribute to a cumulative water quality impact during construction.

During project operation, the proposed project could contribute to degradation of water quality and a cumulative impact if the project altered land use such that the type and concentration of pollutants in storm water runoff increased. Some of the areas within the project vicinity (i.e., Sacramento Railyards, portions of West Sacramento) are currently unpaved, and new development projects would increase impervious surface area that would result in increased storm water runoff. Projects would be consistent with municipal storm water programs for Sacramento, West Sacramento, and Caltrans, and therefore would include post-construction design measures, such as LID and vegetative areas to allow for infiltration and water quality

treatment. The proposed project does not represent a significant departure from the existing land use of the area nor a substantial increase in the impervious surface area. Storm water runoff would be directed to existing storm water collection systems. Therefore, the proposed project would not contribute to a cumulative water quality impact during operation.

Based on the above, cumulative impacts on surface water quality, and the project's contribution to cumulative impacts on surface water quality, would not be cumulatively considerable.

4.5.2 Contribution to Significant Groundwater or Storm Water Drainage Capacity Impacts

4.5.2.1 Groundwater

Groundwater recharge in the Sacramento Valley Groundwater Basin occurs primarily through streamflow infiltration and direct recharge from soil infiltration in pervious areas. Most future projects in the groundwater basin would be redevelopment or infill projects in highly urbanized areas where recharge does not occur. Development in highly urbanized areas would not be expected to substantially increase the amount of impervious surfaces. Because this development would occur primarily in already urbanized areas with existing impervious surfaces, groundwater recharge from percolating rainfall potential would not be adversely affected, and indirect lowering of the local groundwater table is not likely to occur. However, development in areas without existing impervious surfaces would affect groundwater recharge and may result in cumulatively considerable impacts on groundwater.

Excavations requiring dewatering and subsurface features of new buildings in the project area served by the CSS to the Sacramento River, and the separated storm water system, are expected to require some level of dewatering during construction and/or operation because of shallow groundwater conditions. It is possible that dewatering would occur concurrently for various construction projects in the area. This could cause localized shifts in groundwater patterns that could cause areas of degraded groundwater quality to migrate. However, the dewatering protocol established by the cities and enforced at the city level would apply to the proposed project and other development where dewatering is needed within the cities. City staff would review all permit applications for dewatering. This would enable the Cities to determine the volumes and frequencies of discharges that would be allowed to the CSS or separated storm water system from each project to ensure that capacity is not exceeded, water quality violations do not occur, and local groundwater levels do not shift substantially.

Therefore, cumulative impacts on groundwater supply and quality, and the project's contribution to cumulative impacts on groundwater supply and quality would not be cumulatively considerable.

4.5.2.2 Storm Drainage Capacity

Planned development could increase the rate and volume of storm water runoff due to the overall increase in impervious surfaces. Increases in the rate or volume of storm water runoff can cause localized flooding if the storm drain capacity is exceeded, or if flows exceed channel capacities and are conveyed to overbank areas where flood storage may not be available. Proposed projects within the Cities of Sacramento and West Sacramento are required to comply with the stormwater drainage requirements in order to maintain adequate drainage system capacity to convey 100-year peak flows. For the most part, projects with potential cumulative impacts would occur in areas that are already highly developed with impervious surfaces. Therefore, changes in flows that could increase localized flood risk would not be expected to be substantial. The project area is subject to flooding during 50-year, 100-year, and 200-year flood events. New development, including the proposed project, could increase impervious areas and result in greater flood flows, place impediments to flow that would raise flood levels, and/or place additional people or structures within flood-prone areas. Existing regulations and requirements, such as DWR's FloodSafe California Urban Levee Design Criteria and Caltrans' Hydraulic Design Criteria, require site-specific actions to avoid increasing flood levels and placing people or structures at risk of flood flows up to the current 100-year event condition. No current regulatory requirements fully address long-term flood risks due to accelerated sea level rise. Thus, it cannot be guaranteed that project and cumulative development requirements would address all contingencies, and the potential exists for significant flooding impacts both now and in the future. Project design would accommodate 50-year, 100-year and 200-year flood events.

All projects with potential cumulative impacts on storm drainage capacity would be required to include design features that would reduce flows to pre-project conditions, according to Caltrans MS4 Permit requirements, and other municipal storm water requirements. The proposed project would be required to design a storm water drainage system in compliance with these requirements. Thus, cumulative impacts on storm drainage capacity would likely be less than significant, and the project's contribution to impacts on storm drainage capacity would not be cumulatively considerable.

Chapter 5 Avoidance and Minimization Measures

5.1 Introduction

Implementation of water quality measures (management measures and BMPs) are required to address project-related water quality impacts during construction, operation, and maintenance of the bridge. Key management measures include the following:

- Protect areas that provide important water quality benefits or are particularly susceptible to erosion or sediment loss.
- Minimize the potential for erosion via limiting land disturbances such as clearing and grading and cut/fill.
- Preserve any existing terrain providing desirable drainage courses or effective filtration.
- Limit disturbance of natural drainage features and vegetation.
- Prepare and implement an approved SWPPP.
- Ensure proper storage and disposal of potential hazardous material.
- Incorporate pollution prevention into operation and maintenance procedures to reduce pollutant loadings to surface runoff.

5.2 Proposed Hydrology and Water Quality Measures

The following measures will be implemented to avoid or minimize potential hydrology and water quality impacts of the proposed project.

5.3 Water Quality Protection Measures

5.3.1 Construction

Construction of the I Street Bridge would involve pile driving; removal of the existing bridge; cofferdam installation and removal; pier installation; and placement of barge spuds; construction of the concrete bridge deck and railing; creation and use of construction staging area(s); operation of heavy construction equipment (e.g., graders, excavators) alongside Sacramento River; road widening and raising; new drainage facilities; embankment construction;

constructing the end bridge abutments; and other related activities. Impacts from these activities would be avoided or minimized because all construction activities within the Sacramento River would comply with a variety of permits and requirements from agencies, including the State Water Board/Central Valley Water Board, USACE, CDFW, as well as the Sacramento County, Yolo County, City of Sacramento, and City of West Sacramento Public Works Departments.

Since the project is greater than one acre, it is required to be covered under the Construction General Permit issued by the State Water Board. The proposed project will implement construction BMPs based on guidance from several resources including the Caltrans Construction Site Best Management Practices Manual (California Department of Transportation 2003), and any other related local stormwater guidance documents.

The project proponent, and/or the construction contractor, will comply with all construction site BMPs specified in the SWPPP and any other permit conditions to minimize introduction of construction-related contaminants and mobilization of sediment in the Sacramento River. Broadly, these BMPs will address soil stabilization, sediment control, wind erosion control, vehicle tracking control, non-storm water management, and waste management practices. The BMPs will be based on the best conventional and best available technology.

The BMPs will be selected to achieve maximum sediment removal and represent the best available technology that is economically achievable and are subject to review and approval by the County. As part of Construction General Permit compliance, the project SWPPP will require the construction contractor to implement, monitor, and maintain appropriate BMPs. Routine inspections will be performed of the construction area to verify the BMPs are properly implemented and maintained. The contractors will be notified immediately if there is a noncompliance issue and will require compliance.

The BMPs will include, but are not limited to, those presented below. The categories provided are based on Construction Site BMP Fact Sheets provided by Caltrans (http://www.dot.ca.gov/hq/construc/stormwater/factsheets.htm) and the Construction BMPs provided in the California Stormwater Quality Association's BMP Handbook (California Stormwater Quality Association 2015).

Scheduling

The project is estimated to be constructed in 30 months starting in 2018. All in-water work within Sacramento River will be conducted during allowable work windows as identified by resource and permitting agencies.

Vehicle & Equipment Fueling and Maintenance

Equipment used in and around drainages and wetlands will be in good working order and free of dripping or leaking engine fluids. All vehicle maintenance will be performed at least 300 feet from the Sacramento River and all drainages and wetlands. Any necessary equipment washing will be carried out where the water cannot flow into the river or other drainages, or wetlands.

Spill Prevention

Potential release or spillage of petroleum products such as diesel fuel, hydraulic fluid, and lubrication greases, from a vehicle or piece of equipment during maintenance or fueling could affect water quality if these petroleum products infiltrate into soil or are washed into nearby storm drains or directly into the Sacramento River. However, given that the volume of petroleum released during an incidental spill on a construction site is typically small (less than 25 gallons) and can be cleaned up immediately, impacts associated with petroleum spills during the construction phase are considered minor. The project proponent will comply with applicable stormwater ordinances, stormwater management plans, the project Spill Prevention, Control, & Countermeasure (SPCC) plan, and BMPs to prevent or minimize the potential release of contaminants into surface waters and groundwater. Implementation of standard construction procedures and precautions for working with petroleum and construction chemicals will further ensure that the impacts related to chemical handling during project construction will be minor. The project will include development and implementation of a hazardous material SPCC plan before construction begins. The plan will include strict onsite handling rules to keep construction and maintenance materials from entering the river, including procedures related to refueling, operating, storing and staging construction equipment and preventing and responding to spills. The plan will also identify the parties responsible for monitoring the spill response. During construction, any spills will be cleaned up immediately according to the spill prevention and countermeasure plan. The County will review and approve the contractors' potential hazardous material SPCC plan before allowing construction to begin.

Hazardous and Concrete Waste Management

The following types of materials will be prohibited from being rinsed or washed into the streets, shoulder areas, or gutters: concrete; solvents and adhesives; thinners; paints; fuels; sawdust; dirt; gasoline; asphalt and concrete saw slurry; heavily chlorinated water.

Material Delivery and Storage

Proper storage and disposal of potential hazardous material will be ensured. Any surplus concrete rubble, asphalt, or other rubble from construction will be taken to a local landfill.

Erosion and Sediment Control

An erosion and sediment control plan will be prepared and implemented for the proposed project. The potential for erosion and sedimentation will be managed using effective construction and engineering BMPs. These practices include stabilizing the soil surface, reducing erosive energy of surface flow, filtering runoff, and capturing sediment-laden water. The project proponents will require their construction contractors to implement BMPs included in the SWPPP and comply with grading ordinances that protect the river from erosion and sedimentation. The following is a list of potential erosion and sediment control measures that would likely be implemented to reduce potential project water quality impacts and comply with the Construction General Permit:

- Silt Fence: Temporary erosion control measures, such as sandbagged silt fences, will be applied throughout construction of the proposed project and will be removed after the working area is stabilized or as directed by the engineer. Soil exposure will be minimized through use of temporary BMPs, groundcover, and stabilization measures.
- Wind Erosion Control: Exposed dust-producing surfaces will be sprinkled daily, if necessary, until wet; this measure will be controlled to avoid producing runoff. Paved roads will be swept daily following construction activities.
- Hydroseeding: An appropriate seed mix of native species will be planted on disturbed areas upon completion of construction.
- Soil Binders: Cover or apply nontoxic soil stabilizers to inactive construction areas (previously graded areas inactive for 10 days or more) that could contribute sediment to waterways.
- Stockpile management: Enclose and cover exposed stockpiles of dirt or other loose, granular construction materials that could contribute sediment to waterways. Material stockpiles will be located in non-traffic areas only. Side slopes will not be steeper than 2:1. All stockpile areas will be surrounded by a filter fabric fence and interceptor dike
- Avoid earth or organic material from being deposited or placed where it may be directly carried into the channel.

Dewatering Operations

Before discharging any dewatered effluent to surface waters, the applicant or its contractors will obtain a Low Threat Discharge and Dewatering NPDES permit from the Central Valley Regional Water Quality Control Board. As part of the permit, the project proponent will design and implement measures as necessary so that the discharge limits identified in the relevant permit are met. Should dewatering be discharged into the Sacramento River or nearby storm drains, the

Low Threat Discharge and Dewatering NPDES permit would require proper disposal of the water. As a performance standard, these measures will be selected to achieve maximum sediment removal and represent the best available technology that is economically achievable. Implemented measures may include the retention of dewatering effluent until particulate matter has settled before it is discharged, use of infiltration areas, and other BMPs. For example, dewatered turbid water could be diverted to a settling tank, and/or treated in a manner to ensure compliance with water quality requirements prior to being discharged to infiltration basins or re-used for dust control or landscape irrigation. Final selection of water quality control measures will be subject to approval by the Central Valley Regional Water Quality Control Board.

In addition, Caltrans has a Field Guide to Construction Site Dewatering that provides the Resident Engineer with step-by-step instructions for overseeing dewatering operations on the construction site. All aspects of dewatering are addressed, from the selection of an appropriate dewatering management option to ensuring compliance with requirements specified in the Caltrans NPDES permit, Sacramento County MS4 Permit, and the State Water Board's Small MS4 Permit for operations, maintenance, and reporting. Detailed information about sediment removal methods and technologies are provided in Appendix B of the Field Guide.

Water Quality Monitoring

Baseline turbidity, pH, specific conductance, and temperatures in Sacramento River will be measured. As required by the Regional Water Board, exceedances of water quality standards specified in the Basin Plan for the Sacramento and San Joaquin River Basins will be avoided.

Implementation of the SWPPP, Caltrans BMPs, and the cities of Sacramento and West Sacramento stormwater guidance measures will minimize the potential for construction-related surface water pollution and ensure that water quality in the Sacramento River will not be compromised by erosion and sedimentation during construction. A 401 Water Quality Certification will be obtained from the Central Valley Water Board, which may contain additional BMPs and water quality measures to ensure the protection of water quality.

5.3.2 Operation

The new bridge and road design will incorporate permanent erosion control elements, primarily permanent vegetation, to ensure that stormwater runoff does not cause soil erosion. Implementation of the project-specific long-term avoidance and minimization measures and design BMPs will also reduce or avoid impacts on water quality.

The proposed project will adhere to the requirements of the Caltrans NPDES Permit, Sacramento County MS4 Permit, and the State Water Board's Small MS4 Permit and ensure that stormwater

pollution during operation and maintenance of the project will be minimal by implementing design measures recommended in Caltrans guidance documents, and post-construction BMPs. Standard facilities used to handle stormwater onsite will include an array of structural elements or facilities that will serve to manage, direct, and convey the stormwater.

Project design measures, such as LID facilities, are a means of complying with municipal stormwater permits. The proposed project design includes the installation of vegetated slopes and swales along bridge approaches where water will be treated through soil infiltration and vegetative uptake. All such stormwater drainage facilities will be designed per the Caltrans and BMP guidelines to sufficiently accommodate large storm flows. The implementation of BMPs will minimize impacts to water quality during long-term operations at the site. The BMPs include measures to ensure the post-construction controls (e.g., source controls and site design) are in place to minimize water quality impacts. Regulatory compliance measures, as discussed above, will minimize the potential for surface water degradation over the long term. The project proponent will also obtain a 401 Water Quality Certification from the Central Valley Water Board that may include additional BMPs.

5.3.3 Groundwater Protection Measures

The proposed project will not substantially affect groundwater resources because, if excavations are required, they would only intersect the shallow water table temporarily with only localized and inconsequential effects to the regional groundwater system. While small amounts of construction-related dewatering are covered under the General Construction Permit, the proposed project may also need to comply with the Central Valley Regional Water Quality Control Board's Low Threat General Dewatering Permit. In addition, Caltrans has a Field Guide to Construction Site Dewatering that provides the Resident Engineer with step-by-step instructions for overseeing dewatering operations on the construction site. All aspects of dewatering are addressed, from the selection of an appropriate dewatering management option to ensuring compliance with Caltrans NPDES permit requirements for operations, maintenance, and reporting.

5.3.4 Drainage Control Measures

The new bridge and roadway approaches would involve minor additional impervious surface area compared to the existing structures once construction is completed. Potential new surface flows from the project would be designed so as to mimic pre-project flows. Drainage system improvements would be designed to accommodate storm drain infrastructure capacities and prevent ponding. The proposed project will be designed in accordance with the objectives of Caltrans NPDES Permit requirements, and related stormwater requirements to reduce runoff and

the volume of entrained sediment. In addition, the potential minimal increase in impervious area would not cause on- or off-site flooding.

Attachment A Construction General Permit SWPPP Risk Level Assessment

- Summary of Risk Level Determination
- Risk Determination Worksheet (State Water Resources Control Board)
- Isoerodent Map of California (State Water Resources Control Board)
- Web Soil Survey (USDA Natural Resources Conservation Service)

A. CONSTRUCTION GENERAL PERMIT SWPPP RISK LEVEL ASSESSMENT

The General NPDES Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities (Order 2009-0009-DWQ) (Construction General Permit) regulates stormwater discharges for construction activities CWA Section 402. Dischargers whose projects disturb 1 or more acres of soil, or whose projects disturb less than 1 acre but are part of a larger common plan of development that in total disturbs 1 or more acres, are required to obtain coverage under the Construction General Permit. The Construction General Permit requires the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP). The Construction General Permit separates projects into Risk Levels 1, 2, or 3. Risk levels are determined during the planning and design phases, and are based on potential erosion and transport to receiving waters. Requirements apply according to the Risk Level determined. For example, a Risk Level 3 (highest risk) project would require compulsory storm water runoff pH and turbidity monitoring, and pre- and post-construction aquatic biological assessments during specified seasonal windows.

A.1 Summary

The I Street Bridge Replacement Project(proposed project) involves greater than one acre of land disturbance, and therefore a Stormwater Pollution Prevention Plan (SWPPP) is required for the proposed project. More information on SWPPP requirements is provided in Section 2.1, *Section 402—National Pollutant Discharge Elimination System*. A construction site risk assessment has been performed for the Project SWPPP and the resultant risk level is **Risk Level 2**. The risk level was determined based on the procedure described in the General Permit and based two major elements – (1) project sediment risk (the relative amount of sediment that can be discharged, given the project and location details) and (2) receiving water risk (the risk sediment discharges pose to the receiving waters). Project Sediment Risk is determined by multiplying the R, K, and LS factors from the Revised Universal Soil Loss Equation (RUSLE) to obtain an estimate of project-related bare ground soil loss expressed in tons/acre. Receiving water risk is based on whether a project drains to a sediment-sensitive water body. A sediment-sensitive water body is either on the most recent 303d list for water bodies impaired for sediment; has a USEPA-approved Total Maximum Daily Load implementation plan for sediment; or has the beneficial uses of COLD, SPAWN, and MIGRATORY.

Tables A.1 and A.2 summarize the sediment and receiving water risk factors and document the sources of information used to derive the factors. RUSLE Method 2 was used to determine these values.

Table A.1. Summary of Sediment Risk

RUSLE Factor	Value	Method for Establishing Value
R	105	EPA website: http://cfpub.epa.gov/npdes/stormwater/LEW/lewCalculator.cfm.
K	0.14	Weighted average for surface layer of soil map units
LS	0.20	Field observations and LS Table from Sediment Risk Factor Worksheet in General Permit. Calculation assumes 1% slope (based on NRCS data) and 300 foot slope length.
Total Predicted Sediment Loss (tons/acre)		2.94
Overall Sediment Risk Low Sediment Risk < 15 tons/ acre Medium Sediment Risk >= 15 and < 75 tons/acre High Sediment Risk >= 75 tons/acre		☒ Low ☐ Medium ☐ High

Table A.2. Summary of Receiving Water Risk

Receiving Water Name	303(d) Listed for Sediment Related Pollutant(1)	TMDL for Sediment Related Pollutant(1)	Beneficial Uses of COLD, SPAWN, and MIGRATORY(1)
Sacramento-San Joaquin Delta	☐ Yes ☒ No	☐ Yes ☒ No	☒ Yes ☐ No
Middle River	☐ Yes ☒ No	☐ Yes ☒ No	☐ Yes ☒ No
Overall Receiving Water Risk			☐ Low ☒ High

(1) If yes is selected for any option the Receiving Water Risk is High

A.2 Project Sediment Risk

A.2.1 The R-Factor

The R factor is computed by using the following parameters:

Estimated construction start date: May 1, 2018

Estimated construction end date (date of final stabilization): May 1, 2021

Erosivity Index (EI) distribution zone (Figure 1 of the Construction General Permit Risk Assessment R-Factor Calculation Notification): 23

EI Value (Table 1, the Erosivity Index (EI) Table of the Construction General Permit Risk Assessment R-Factor Calculation Notification): 100% X 3 years = 300% (if project lasts for one year, EI value is 100%)

Isoerodent Value for Project Area (Isoerodent Map for California in the Construction General Permit Risk Assessment R-Factor Calculation Notification): 35

R Factor = (300%)*(35) = 105

A.2.2 The K-Factor

The K factor is computed by using the following parameters:

K-values were provided per soil unit type via a Natural Resources Conservation District (NRCS) Web Soil Survey. A weighted average was derived from the K-values based on the proportionate areas per soil unit type within the total area of influence (AOI) (291.1 acres). The weighted average was determined to be 0.12, which is characterized as a low K value within the range (about 0.05 to 0.15) of fine-textured soils that are high in clay and the particles are resistant to detachment. Table A.3 shows a summary of all the map units with the project area of influence from which the K-value was calculated.

Table A.3. Determination of K-Value for Project Area of Influence

Map Unit Symbol[1]	Name[1]	K-Value[1]	Weighted K-Values	Acres in AOI[1]
Sacramento County, California (CA067)				
186	Orthents-Urban land complex, 0 to 2 percent slopes	--	0	23
227	Urban Land	--	0	3.8
Yolo County, California (CA113)				
La	Lang sandy loam	0.24	1.848	7.7
Lb	Lang sandy loam, deep	0.24	2.712	11.3
So	Sycamore silt loam	0.43	2.795	6.5
TOTAL			7.4	52.3
Weighted Average			0.14	

[1] Source: Natural Resources Conservation District (NRCS). 2013. Web Soil Survey. Available: http://websoilsurvey.nrcs.usda.gov/app/HomePage.htm. Accessed: March 27, 2013.

Key:
"—" = not specified
AOI = Area of Influence

A.2.3 The LS-Factor

The LS Factor was determined based on the following factors:

Based on the NRCS soil unit map (see attached), slopes within the Project area are 0-2%. Therefore a 1% slope was assumed. Because a topographical map was not available to determine the length of slope, because there is very little microtopography (generally flat terrain with little variation), a 300-foot slope length was used. The average slope percentage and slope length was used with the LS Factors for Construction Sites Table to determine the LS Factor of 0.20.

A.3 Receiving Water Risk

The Receiving water risk was determined to be "High" based on the fact that the Sacramento River has the designated existing beneficial uses of COLD, SPAWN, and MIGRATORY, which is included in the criteria for receiving water risk determination.

5			1. GIS Map Method - EPA Rainfall Erosivity Calculator & GIS map				
6			2. Individual Method - EPA Rainfall Erosivity Calculator & Individual Data				
7		**Step 2**	Determine Receiving Water Risk via one of the options listed:				
8			1. GIS map of Sediment Sensitive Watersheds provided				
9			2. Site Specific Analysis (support documentation required)				
10		**Step 3**	Determine Combined Risk Level				
11							

	A	B	C
1	**Sediment Risk Factor Worksheet**		**Entry**
2	**A) R Factor**		
3	Analyses of data indicated that when factors other than rainfall are held constant, soil loss is directly proportional to a rainfall factor composed of total storm kinetic energy (E) times the maximum 30-min intensity (I30) (Wischmeier and Smith, 1958). The numerical value of R is the average annual sum of EI30 for storm events during a rainfall record of at least 22 years. "Isoerodent" maps were developed based on R values calculated for more than 1000 locations in the Western U.S. Refer to the link below to determine the R factor for the project site.		
4	http://water.epa.gov/polwaste/npdes/stormwater/Welcome-to-the-Rainfall-Erosivity-Factor-Calculator.cfm		
5	**R Factor Value**		105
6	**B) K Factor (weighted average, by area, for all site soils)**		
7	The soil-erodibility factor K represents: (1) susceptibility of soil or surface material to erosion, (2) transportability of the sediment, and (3) the amount and rate of runoff given a particular rainfall input, as measured under a standard condition. Fine-textured soils that are high in clay have low K values (about 0.05 to 0.15) because the particles are resistant to detachment. Coarse-textured soils, such as sandy soils, also have low K values (about 0.05 to 0.2) because of high infiltration resulting in low runoff even though these particles are easily detached. Medium-textured soils, such as a silt loam, have moderate K values (about 0.25 to 0.45) because they are moderately susceptible to particle detachment and they produce runoff at moderate rates. Soils having a high silt content are especially susceptible to erosion and have high K values, which can exceed 0.45 and can be as large as 0.65. Silt-size particles are easily detached and tend to crust, producing high rates and large volumes of runoff. Use Site-specific data must be submitted.		
8	Site-specific K factor guidance		
9	**K Factor Value**		0.14
10	**C) LS Factor (weighted average, by area, for all slopes)**		
11	The effect of topography on erosion is accounted for by the LS factor, which combines the effects of a hillslope-length factor, L, and a hillslope-gradient factor, S. Generally speaking, as hillslope length and/or hillslope gradient increase, soil loss increases. As hillslope length increases, total soil loss and soil loss per unit area increase due to the progressive accumulation of runoff in the downslope direction. As the hillslope gradient increases, the velocity and erosivity of runoff increases. Use the LS table located in separate tab of this spreadsheet to determine LS factors. Estimate the weighted LS for the site prior to construction.		
12	LS Table		
13	**LS Factor Value**		0.20

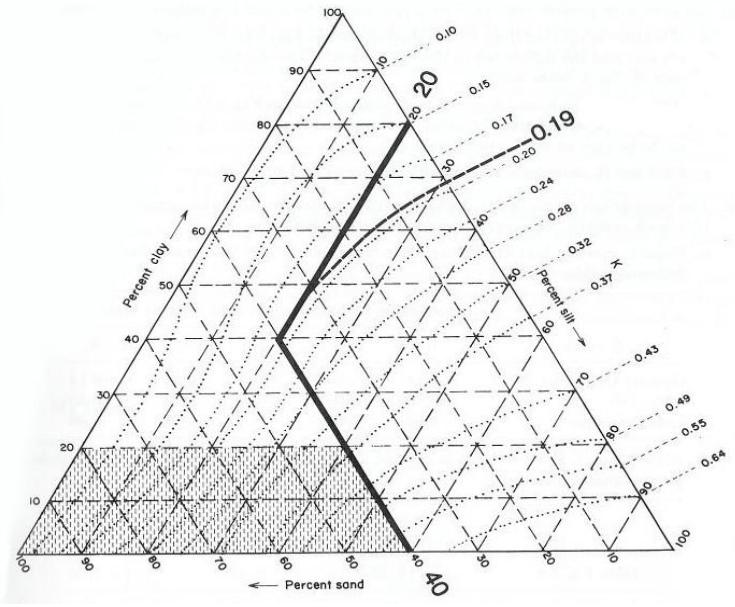
Project Combined Risk:	**Level 2**

Soil Erodibility Factor (K)

The K factor can be determined by using the nomograph method, which requires that a particle size analysis (ASTM D-422) be done to determine the percentages of sand, very fine sand, silt and clay. Use the figure below to determine appropriate K value.



Erickson triangular nomograph used to estimate soil erodibility (K) factor.
The figure above is the USDA nomograph used to determine the K factor for a soil, based on its texture (% silt plus very fine sand, % sand, % organic matter, soil structure, and permeability). *Nomograph from Erickson 1977 as referenced in Goldman et. al., 1986.*

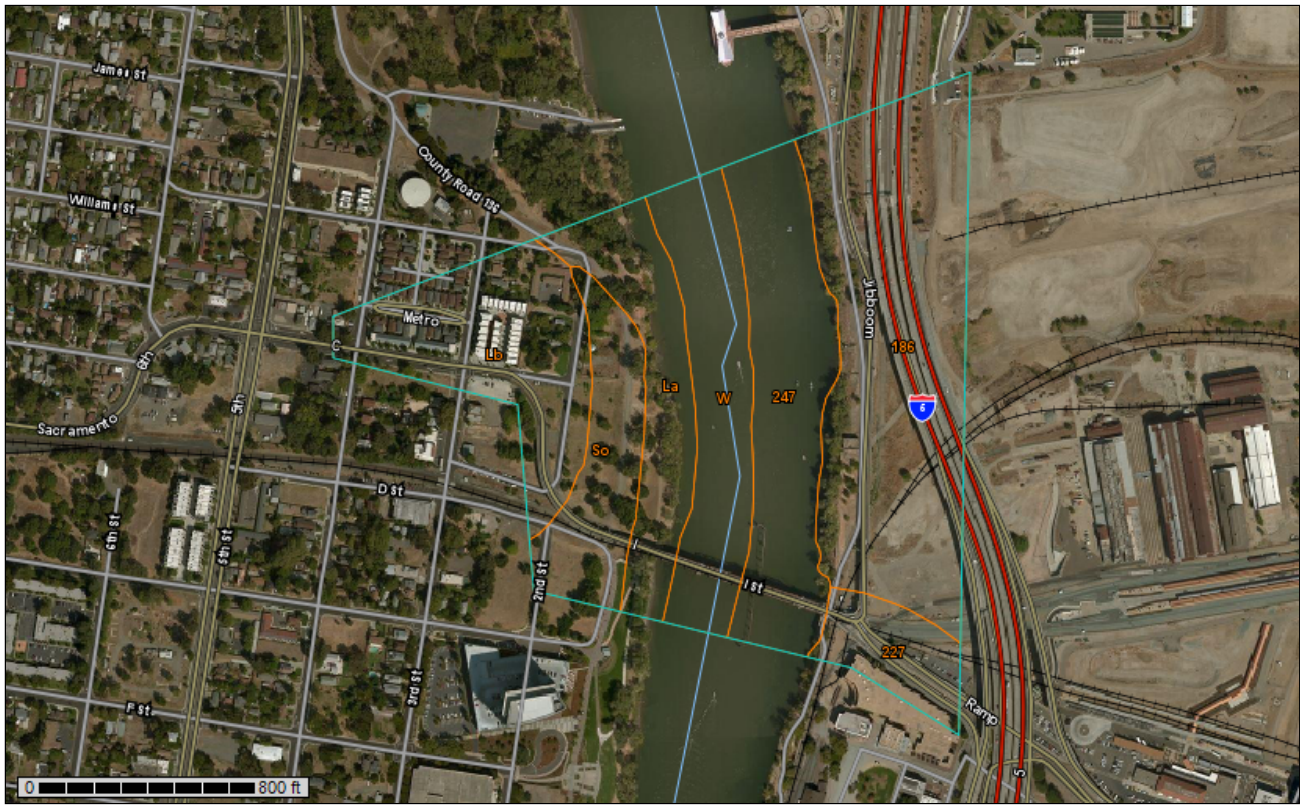
Soil Map

Scale (not to scale)



Warning: Soil Map may not be valid at this scale.

You have zoomed in beyond the scale at which the soil map for this area is intended to be used. Mapping of soils is done at a particular scale. The soil surveys that comprise your AOI were mapped at scales ranging from 1:20,000 to 1:24,000. The design of map units and the level of detail shown in the resulting soil map are dependent on that map scale.

Enlargement of maps beyond the scale of mapping can cause misunderstanding of the detail of mapping and accuracy of soil line placement. The maps do not show the small areas of contrasting soils that could have been shown at a more detailed scale.

1.0 INTRODUCTION

1.1 Purpose of the Air Quality Study Report

The purpose of the Air Quality Study Report is to identify the air quality and climate change effects of the I Street Bridge Replacement Project (proposed project). Both short-term construction emissions and long-term effects related to the ongoing operation of the alternatives are discussed in this section. This analysis focuses on air pollution from two perspectives: daily emissions and pollutant concentrations. Emissions refer to the quantity of pollutants released into the air. Concentrations refer to the amount of pollutant material per volumetric unit of air.

1.2 Scope and Content of the Air Quality Study Report

The Air Quality Study Report includes:

- A project description documenting design assumptions that are relevant to the air quality analysis. The project description includes a description of the alternatives under consideration.
- Regional meteorology and climate information, including a description of the area's topography.
- A description of applicable regulations and agencies involved with air quality in the area. The description outlines air quality standards on both the federal and State levels.
- A discussion of the project area and affected environment, including monitor locations and data, area conformity designations and classifications, and the location of sensitive receptors.
- Project-level transportation conformity documentation related to the Federal Clean Air Act (FCAA).
- Results of air quality analyses, including a description of methodologies and assumptions.
- Potential impacts of the project on air quality: direct, indirect, temporary, and permanent.
- Potential avoidance, minimization and/or mitigation measures.

1.3 Summary

The Cities of Sacramento and West Sacramento together have recognized the need for more river crossings. The I Street Bridge Replacement project includes construction of a new bridge upstream of the existing I Street Bridge. The new bridge would cross the Sacramento River between the Sacramento Railyards area and the West Sacramento Washington planned developments and provide a new bicycle, pedestrian, and automobile crossing. The existing I Street Bridge would continue to be used by the railroad. The approach viaducts to the existing I Street Bridge would be demolished, which should result in better access to the water front in both cities.

The findings of the Air Quality Study Report are as follows:

Project Operations

- Transportation Conformity - The proposed project is exempt from all Transportation Conformity requirements per Section 93.126 in Title 40 of the Code of Federal Regulations (CFR). The specific exemption is related to widening narrow pavements or reconstructing bridges without additional travel lanes. Sacramento Area Council of Governments (SACOG) confirmed this finding on August 23, 2016.
- Regional Emissions - Regional emissions were estimated for volatile organic compounds (VOC), nitrogen oxides (NO_X), carbon monoxide (CO), particulate matter 2.5 microns or less in diameter ($PM_{2.5}$), particulate matter 10 microns or less in diameter (PM_{10}), and greenhouse gases (GHGs). The emissions analysis indicates that the Build Alternatives would generally result in a negligible change in emissions (compared to the No Build Alternative in 2020 and 2040.
- Mobile Source Air Toxics (MSAT) - According to Federal Highway Administration (FHWA) guidance, the proposed project is classified as a Project with Low Potential MSAT Effects. There would be no appreciable difference in overall MSAT emissions among the various Build Alternatives There could be increases in MSAT levels in a few localized areas where vehicle miles traveled (VMT) increases. However, vehicle and fuel regulations will bring about significantly lower MSAT levels for the project area in the future than today.
- Naturally Occurring Asbestos (NOA) and Structural Asbestos - There is no occurrence of asbestos reported within 25 miles of the project area. Although it is not anticipated that construction activity would encounter NOA, the proposed project dust control measures would effectively control unanticipated NOA exposure through a variety of required control measures including watering. In addition, it is not anticipated that construction activity would encounter structural asbestos.
- Lead - It is not anticipated that construction of the proposed project would involve disturbance of soils containing high levels of aerially-deposited lead, painting or modification of structures with lead-based coatings using sandblasting and other activities related to lead paint removal or disturbance.

Project Construction

Construction emissions would include fugitive dust and exhaust from equipment, trucks, and worker vehicles. Construction activity would generate emissions related to VOC, NO_X, CO, $PM_{2.5}$, PM_{10}, and GHGs. To control the generation of construction-related PM_{10} emissions, the project proponent will follow Standard Specification Section 14, "Environmental Stewardship," which addresses the contractor's responsibility on many items of concern, such as: air pollution; protection of lakes, streams, reservoirs, and other water bodies; use of pesticides; safety; sanitation; convenience for the public; and damage or injury to any person or property as a result of any construction operation. Section 14-9.02, which includes specifications relating to air pollution control by complying with air pollution control rules, regulations, ordinances, and statutes that apply to work performed under the contract, including air pollution control rules, regulations, ordinances, and statutes provided in Government Code Section 11017 (Public Contract Code Section 10231). Section 14-9.03 is directed at controlling dust. In addition, Caltrans Standard Specifications for construction (Sections 10 and 18 for dust control and Section 39-3.06 for asphalt concrete plants) will be adhered to in order to reduce emissions generated by construction equipment. Implementation of the following avoidance, minimization, and/or mitigation measures would reduce fugitive dust air quality emissions resulting from construction activities:

AQ-1 The contractor shall obtain all necessary Sacramento County and Yolo County permits and approvals and shall follow all required County laws and procedures and respect to best management practices, grading and excavation for the proposed project and all construction-related and emission-generating activities.

AQ-2 Construction of the project shall comply with Sacramento Metropolitan Air Quality Management District (SMAQMD) and Yolo-Solano Air Quality Management District (YSAQMD) Basic Construction Emission Control Practices, Exhaust Control Practices, and Fugitive PM Dust Control Practices.

AQ-3 Construction activity within The Railyards Specific Plan area shall comply with the mitigation measures contained in the adopted Mitigation Monitoring and Reporting Plan for The Railyards development (City of Sacramento 2007).

2.0 PROJECT DESCRIPTION

2.1 Project Location

The proposed project is located over the Sacramento River between Sacramento and West Sacramento, approximately 1,000 feet north of the existing I Street Bridge (**Figure 2-1**). The proposed project limits starting within the City of Sacramento consist of Railyards Boulevard from 200 feet east of Bercut Drive on the east, continuing west over the Sacramento River into the City of West Sacramento along C Street, and terminating approximately 100 feet west of the 5th Street intersection. The proposed project limits also extend along Bercut Drive approximately 500 feet north of Railyards Boulevard, along Jibboom Street 550 feet north of Railyards Boulevard and 300 feet south of Railyards Boulevard, along 3rd Street 50 feet north and south of C Street, along 4th Street 50 feet north and south of C Street, and along 5th Street 50 feet north and south of C Street. The total length of the proposed project is approximately 0.42 miles along C Street and Railyards Boulevard.

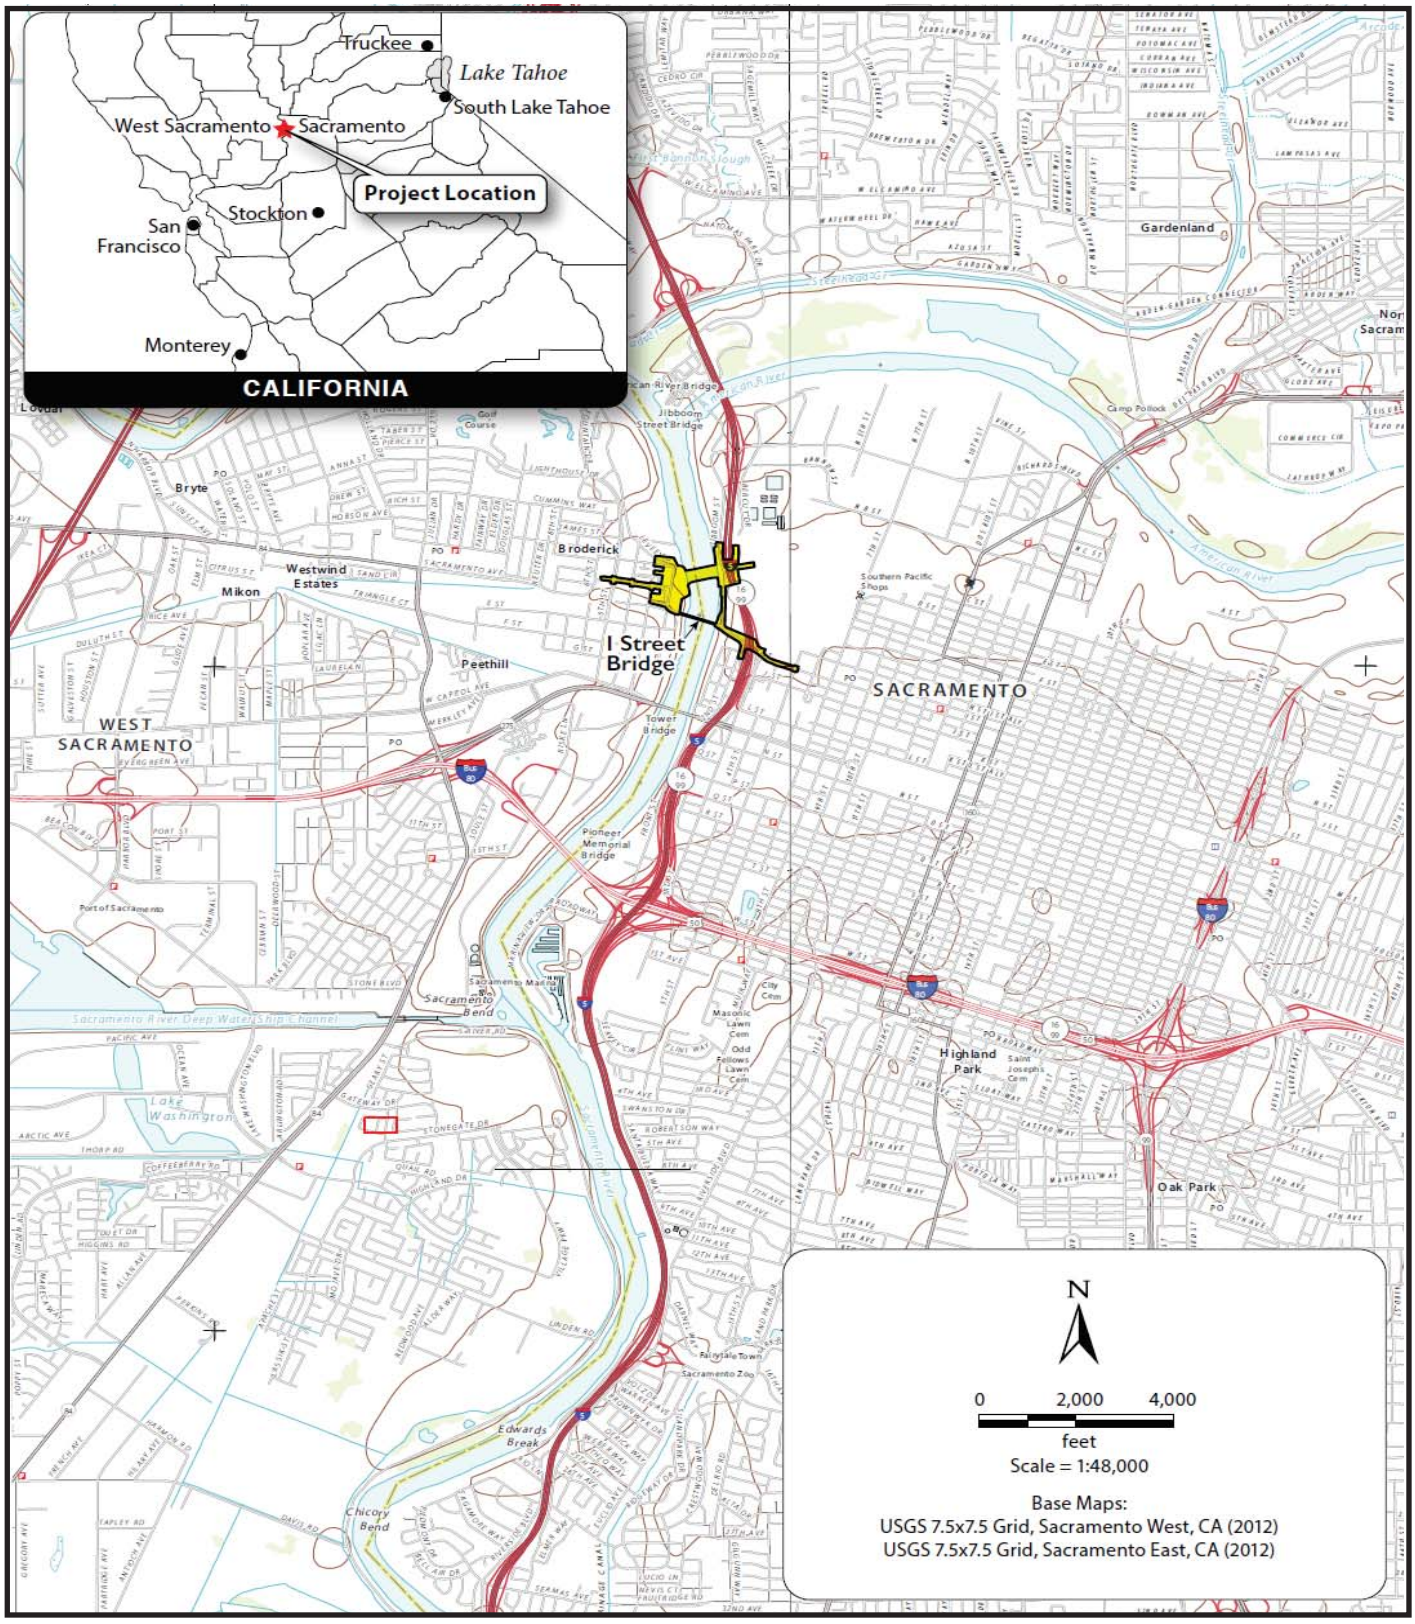
2.2 Purpose and Need

The proposed project would construct a new bridge over the Sacramento River between Sacramento and West Sacramento to replace the vehicle crossing that is currently provided by the existing I Street Bridge. Construction of the proposed project has independent utility; the proposed project is not dependent on other projects or improvements to meet the purpose and need.

2.2.1 Purpose

The purpose and objectives of the project are listed below.

- The project should construct a new public crossing of the Sacramento River north of the Union Pacific Railroad-owned I Street Bridge from C Street in the City of West Sacramento to Railyards Boulevard in the City of Sacramento, consistent with the adopted findings of the Sacramento River Crossings Alternatives Study for Bridge Location 2 in the North Market Area.
- The new bridge should meet the requirements of the Neighborhood Friendly Bridge definition that the City of Sacramento City Council adopted by resolution on October 18, 2011, which is defined by the following elements.
  - A facility whose primary function is local connectivity rather than regional travel and primarily serves short local trips.
  - A bridge which serves all users, including motorists, bicyclists, pedestrians, low energy vehicles, and public transit riders.
  - A bridge with aesthetics and dimensions which are architecturally pleasing and contextually appropriate for the adjacent neighborhoods.
  - A bridge that does not exceed or expand the already-planned capacity of the approach roadways (i.e., no widening of approaches just to accommodate bridge flows).
  - A facility which is designed with a target speed equal to or less than the approach roadways.
  - A bridge which reduces the growth in vehicle miles traveled in the adjacent communities.



SOURCE: ICF International, 2015.

I-Street Bridge Replacement Project
Air Quality Study Report
CALIFORNIA DEPARTMENT OF TRANSPORTATION

FIGURE 2-1

REGIONAL LOCATION

  - A bridge that does not connect directly to streets which are primarily residential in character.
  - A bridge that is consistent with the Need and Purpose statement [the adopted Sacramento River Crossings Alternatives Study statement] as articulated.

- In addition to the Neighborhood Friendly Bridge definition, the project should include pedestrian and bicycle facilities in the new public crossing that meet Americans with Disabilities Act (ADA) requirements, and facilitate connections to and from the new crossing and the Sacramento River Parkway and Riverfront Park trails.
- The proposed project also would need to construct a movable bridge that satisfies the vertical clearance and river navigation requirements of the U.S. Coast Guard (USCG).
- The project design should not preclude future addition of a streetcar, a separate, stand-alone project being developed by Sacramento and West Sacramento.
- The new bridge also is intended to improve the connectivity to, and accessibility of, businesses, recreational areas, and new or redevelopment opportunity sites located in the urban core of Sacramento and West Sacramento.

2.2.2 Need

The proposed project is needed for the following reasons.

- The existing I Street Bridge does not fully comply with current design and traffic operation standards due to the following conditions.
  - I Street Bridge limits or restricts traffic capacity and multimodal use. The current bridge width is not sufficient to provide adequate traffic operations, bicycle lanes, or the ability for transit service across the bridge.
  - The I Street Bridge and the four associated approach structures are on the federal eligible bridge list for federal funds for replacement and/or rehabilitation through the Highway Bridge Program (HBP). The I Street Bridge has been classified as functionally obsolete, and the existing approach structures have been classified as structurally deficient. The Sacramento and West Sacramento have decided to pursue replacement through the HBP.
  - As adopted by the Sacramento City Council, new crossings of the Sacramento River between the Cities Sacramento and West Sacramento shall be Neighborhood Friendly. In coordination with staff from the City of West Sacramento and SACOG, the definition for a Neighborhood Friendly Bridge was developed by the City of Sacramento and the Sacramento City Council adopted the definition by resolution in October 2011. The replacement bridge structure is required to be consistent with the Neighborhood Friendly Bridge definition.
  - In addition to the Neighborhood Friendly Bridge requirements, lack of ADA compliance, non-standard and non-continuous sidewalks, and lack of bicycle facilities discourage walking and bicycling on the existing I Street Bridge.
  - Section 9 of the Rivers and Harbors Act requires any local, State, or federal agency planning to construct a bridge over a navigable waterway to apply for a bridge permit through the USCG. The USCG requires the new bridge to meet or exceed the existing vertical clearance along the river, which is currently set by the Highway 50 Pioneer Bridge. In order to comply with the Neighborhood Friendly Bridge definition

and meet the USCG requirements for navigation clearance, the new bridge will need to be movable.

- The SACOG 2035 Metropolitan Transportation Plan/Sustainable Communities Strategy (MTP/SCS) identifies that a proposed streetcar will cross over the new bridge from Sacramento to West Sacramento. While the streetcar will be a separate, stand-alone project, the bridge design must not preclude the future addition of a streetcar.
- Limited connectivity to the riverfront reduces the potential to achieve planned urban development and redevelopment of opportunity sites identified in the adopted plans for the Sacramento and West Sacramento.

2.3 Alternatives

This section describes the proposed action and the design alternatives that were developed to meet the identified need through accomplishing the defined purpose(s), while avoiding or minimizing environmental impacts. The alternatives under consideration are one bridge alignment for the new bridge over the Sacramento River and two alternatives for portions of the roadway design in Sacramento.

- City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection
  - Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive
  - Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive
- No-Build (No-Project) Alternative

2.3.1 Build Alternatives

One proposed alignment is for the new bridge to cross over the Sacramento River. A new approximately 860-foot bridge, consisting of two vehicle lanes, on-street Class II bike lanes, and sidewalks along both sides, is proposed. The bridge would include two fixed-span approach structures, approximately 200 feet and 270 feet in length, that tie into the Sacramento and West Sacramento banks of the river, respectively (**Figure 2-2**).

The center span of the bridge would be an approximately 330-foot movable span that meets the USCG requirements. Roadway improvements on Railyards Boulevard in the City of Sacramento and C Street in the City of West Sacramento also are proposed. In Sacramento, two alternatives for portions of the roadway design are being considered. **Figure 2-2**, above, depicts the proposed project and the roadway design alternatives, described below.

- City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection
  - Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive
  - Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

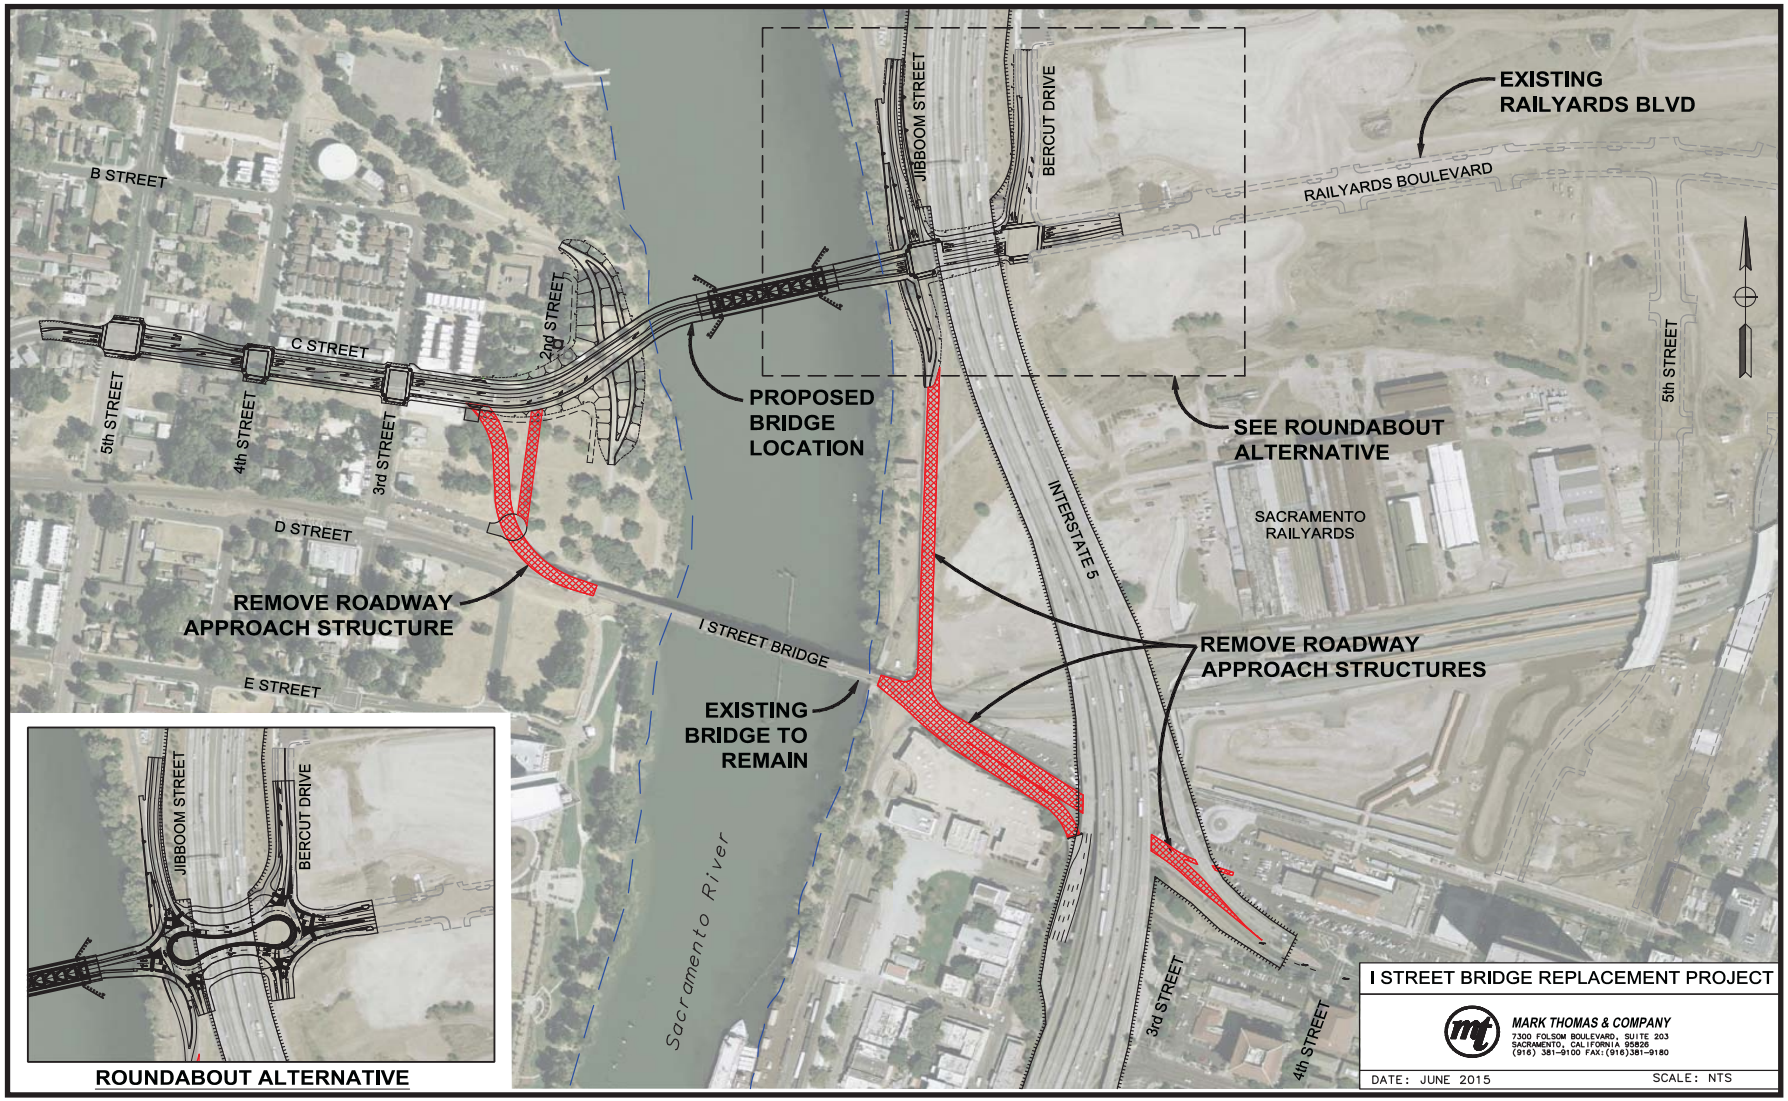


FIGURE 2-2

BUILD ALTERNATIVE

In the City of Sacramento, Alternative 1 consists of a signalized intersection at Jibboom Street and Bercut Drive, while Alternative 2 consists of a roundabout between these two intersections. Beyond the Jibboom Street and Bercut Drive intersections, the remaining project elements and limits in the City of Sacramento are similar under both alternatives.

2.3.1.1 Common Design Features of the Build Alternatives

The proposed project would construct a new bridge over the Sacramento River between Sacramento and West Sacramento to replace the vehicular crossing that is provided by the existing I Street bridge. The proposed project would facilitate vehicular and multimodal traffic over the river in order to reduce traffic congestion, improve safety, and remove a number of structurally deficient or functionally obsolete bridges that have reached the limit of their design life. While the existing I Street Bridge over the Sacramento River would remain in-place, the approach structures leading up to the bridge from both directions would be demolished.

An abbreviated version of the common design features of the build alternatives are listed below. Refer to the Draft Environmental Document for a detailed discussion of the alternatives.

New Bridge Construction and Roadway Modifications

Bridge Construction

The proposed project would construct a new bridge over the Sacramento River. The total bridge length would be approximately 860 feet long, consisting of two vehicle lanes, on-street Class II bike lanes, and sidewalks along both sides of the bridge. The bridge would include two fixed-span approach structures that tie into the Sacramento and West Sacramento banks of the river and are approximately 200 feet and 270 feet in length, respectively. The center span of the bridge would be a movable span that meets the USCG requirements. The movable span is anticipated to be approximately 330 feet in length. The bridge soffit elevation would be set 3 feet above the 200-year water surface elevation to comply with the Central Valley Flood Protection Board freeboard requirements. The two fixed-span approach structures would be 72 feet wide, with a superstructure depth (or total bridge thickness) of approximately 6 feet. Each approach structure would be a two-span bridge.

Roadway Modifications

City of Sacramento. In Sacramento, Bercut Drive would be modified from Railyards Boulevard north approximately 500 feet. Bercut Drive would be designed to have two northbound lanes at the Railyards Boulevard intersection, tapering down to one northbound lane at the northern project limits, and one southbound lane. Improvements to Bercut Drive south of Railyards Boulevard are not part of, nor needed for, the proposed project and would be constructed if needed as part of a separate future project.

Proposed improvements on Jibboom Street would extend 550 feet north of Railyards Boulevard. The roadway would consist of one travel lane in each direction, on-street Class II bike lanes, sidewalk along the west side of the roadway, and retaining walls of various heights along both sides of the road. Extension of Jibboom Street south of Railyards Boulevard is not included with, nor needed for, the proposed project and would be constructed if needed as part of a separate future project.

City of West Sacramento. Between the bridge touchdown location along C Street in West Sacramento and the 4th Street/C Street intersection, the roadway would consist of one westbound travel lane, two eastbound travel lanes (the two eastbound travel lanes would taper down to one eastbound lane east of the 3rd Street intersection), a center left-turn lane, on-street Class II bike lanes, on-street parking along the north side of the roadway, and sidewalks along both sides of the roadway. As the roadway through this section currently consists of the proposed number of travel lanes, the widening through this area is primarily needed to support the Class II bike lanes and wider sidewalks.

Along C Street between 4th Street and 5th Street, the roadway would consist of one travel lane in each direction, left-turn lanes, on-street Class II bike lanes, and sidewalks along both sides of the road. All of the improvements through this section would be accommodated within the existing roadway limits.

Class I Bikeway and Levee Modifications and Improvements

City of Sacramento

The existing Class I Sacramento River Parkway along Jibboom Street would be reconstructed approximately 500 feet north and 300 feet south of Railyards Boulevard as part of the proposed project. In order to maintain a continuous off-street Class I path along this section, the path would be grade-separated under the proposed bridge structure. Cyclists and pedestrians approaching Railyards Boulevard in either direction would have the option to continue along the path under the new structure, avoiding the need to cross the roadway. Cyclists and pedestrians who are traveling along the path also would have the option to connect to Railyards Boulevard and cross over the proposed bridge into West Sacramento or turn east into Sacramento. Due to the limited horizontal clearance between the river and the Interstate-5 (I-5) viaduct structure, retaining walls would be needed along the path to account for the vertical elevation difference between Jibboom Street and the path that continues under the proposed bridge structure. The maximum retaining wall height along the bike path would be 16 feet.

City of West Sacramento

The proposed project would require improvements to the existing levee along the West Sacramento side of the river, where the proposed bridge alignment would connect to C Street. The existing levee does not meet current standards required by Title 23 of the California Code of Regulations. Extending approximately 300 feet north and south of the proposed C Street

alignment, the levee cross-section would be reconstructed to meet current design standards, which would require 3:1 side slopes on the landside and waterside of the levee, and a 20-foot-wide crown at the top of the levee. The levee improvements also would include a slurry cutoff wall extending to a depth of 110 feet below the original ground elevation. In addition, the proposed roadway profile would be approximately 6 feet higher than the original ground elevation as it crosses over the levee. In order to maintain access to the levee for inspection and maintenance services, access roads would be constructed from the new roadway to the top of the improved levee section. The proposed grading for the levee would require relocation of the existing water tower that is located along 2nd Street, just north of the proposed C Street alignment. The tower would be relocated to the northwest, approximately 43 feet from its existing location.

The new levee maintenance road also would serve as the future Class I River Walk Park trail extension in West Sacramento. Similar to the trail improvements proposed as part of the project in Sacramento, the trail would be grade-separated under the proposed bridge structure. Cyclists and pedestrians approaching C Street in either direction would have the option to continue along the trail under the new structure, avoiding the need to cross the roadway. Cyclists and pedestrians who are traveling along the trail also would have the option to connect to C Street to cross over the proposed bridge into Sacramento or head west on C Street.

Structure Demolition and Roadway Modifications

Following completion of the new bridge connections at Railyards Boulevard and C Street, traffic would be diverted to the new bridge, and the four existing approach structures to the I Street Bridge would be removed. Bridge numbers 24C0364L, 24C0364R, 22-0033, and 22C0154 would be demolished and the foundations would be removed to a depth of three feet below the original ground elevation. Encroachment permits from California Department of Transportation (Caltrans) and Union Pacific Railroad would be needed to complete the bridge removal. The existing I Street Bridge is owned and operated by Union Pacific Railroad and would continue to remain in-place and used by trains following construction of the new bridge.

As part of the removal of the existing approach structures, the proposed project would include modifications to I Street within the City of Sacramento from the southbound I-5 on-ramp east to the 5th Street intersection. The modification would include signing and striping revisions, demolition of existing roadway sections that are no longer required, and removal of bridge abutments and foundations.

Staging, Storage, and Proposed Access during Construction

Two staging areas would be used to store materials and equipment during construction, such as pipe materials, precast manholes and drop inlets, steel girders, piles, and rebar, along with the construction equipment when not in use. One area would be located south of Railyards Boulevard under I-5 in Sacramento; the other area would be located west of the landward side of the levee, south of the new bridge location in West Sacramento. The staging area located along Railyards Boulevard would be accessed via the existing intersection at Jibboom Street. The staging area in West Sacramento would be accessed via the existing 2nd Street connection at 3rd Street, south of C Street. The staging areas would be in use throughout the construction duration; the areas would be returned to their pre-project conditions at the completion of the project.

Utility Relocations

A number of public and private utilities would need to be relocated or adjusted to grade as part of the project, including existing water, sewer, gas, electric, and communication facilities within Jibboom Street, Bercut Drive, C Street, and 2nd Street.

Traffic Management and Detours during Construction

While most of the project would be constructed outside of existing roadways, some areas would require temporary detours or staged construction.

Along Jibboom Street at the proposed Railyards Boulevard intersection, the new roadway profile would be raised approximately 6 feet above the original ground elevation. To maintain access to the existing Jibboom Street viaduct south of Railyards Boulevard during the roadway construction, a temporary access road would be needed. The proposed temporary access road would connect to the existing Jibboom Street viaduct abutment approximately 350 feet south of Railyards Boulevard. The temporary road would then continue under I-5 and connect to the Railyards Boulevard/Bercut Drive intersection. The temporary road would require placement of temporary fill material and a roadway structural section that would be removed after construction of the new bridge. Traffic traveling north along Jibboom Street would continue north along Bercut Drive to access the Richards Boulevard/I-5 interchange.

In order to complete the improvements at Jibboom Street and Railyards Boulevard, Jibboom Street would be closed to traffic approximately 600 feet north of Railyards Boulevard. Traffic traveling south along Jibboom Street to continue over the existing I Street Bridge into West Sacramento would be detoured over to Bercut Drive at Richards Boulevard. Traffic would then use the temporary access road to connect to the Jibboom Street viaduct structure. The temporary access road would be in place for approximately two years, after which traffic would use the new roadways and new bridge.

The Sacramento River Parkway trail along Jibboom Street also would require temporary re-routing during construction. The temporary alignment for the trail would follow the temporary Jibboom Street alignment south of Railyards Boulevard. Cyclists and pedestrians would then continue following a detour north along Bercut Drive to Richards Boulevard, where they could then connect back to the Parkway on the west side of I-5. The detour would be in place for approximately two years.

During construction, traffic along C Street would be maintained along the existing approach structure until the new bridge is constructed.

Project Construction Sequence

New bridge and roadway construction would occur first, followed by demolition of the four approach structures that connect to the existing I Street Bridge. Once the new bridge and roadways are constructed, traffic would be diverted to the new bridge in order to allow demolition adjacent to the existing bridge. Construction of the project is expected to take approximately 30 months.

2.3.1.2 Unique Features of Build Alternatives

In both Sacramento and West Sacramento, two alternatives for portions of the roadway design are being considered.

City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection

Alternative 1 consists of a signalized intersection at Jibboom Street and Bercut Drive, while Alternative 2 consists of a roundabout between these two intersections. Beyond the Jibboom Street and Bercut Drive intersections, the remaining project elements and limits are similar under both alternatives.

Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive

Under Alternative 1, Railyards Boulevard would be extended west over the Sacramento River; east of Bercut Drive. Railyards Boulevard would consist of two westbound lanes and one eastbound lane. Between Jibboom Street and Bercut Drive, Railyards Boulevard would consist of two westbound lanes and three eastbound lanes; two eastbound lanes would be trapped into left-turn lanes onto Bercut Drive, and one eastbound lane would continue along Railyards Boulevard. West of the Jibboom Street intersection, Railyards Boulevard would consist of one lane in each direction.

Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

Under Alternative 2, Railyards Boulevard would be extended west over the Sacramento River. East of Bercut Drive, Railyards Boulevard would consist of two westbound lanes and one eastbound lane. Between Jibboom Street and Bercut Drive, Railyards Boulevard would consist of a roundabout with two lanes in each direction. One westbound lane would be a trap onto northbound Jibboom Street, and one westbound lane would continue onto the new bridge. One eastbound lane would be trapped into left-turn lanes onto Bercut Drive, and one eastbound lane would continue along Railyards Boulevard. West of Jibboom Street, Railyards Boulevard would consist of one lane in each direction.

City of West Sacramento Residential Access

The new C Street alignment would cut off access to four residential parcels and one multifamily parcel located along 2nd Street, north of C Street. The project would construct a new connection to C Street approximately 150 feet east of the 3rd Street intersection that would continue north approximately 300 feet. The new connection would then make a 90-degree left turn and connect to 3rd Street approximately 300 feet north of C Street. The proposed access would be consistent with the City of West Sacramento's design standards for a public alley, which consists of 30-foot wide public right of way, supporting a 20-foot travel way, a 5-foot sidewalk, and a 5-foot buffer to adjacent parcels.

2.3.2 No Build Alternative (No Project)

Under the No Build Alternative, the existing I Street Bridge would remain in use for vehicle, bicycle, and pedestrian access between Sacramento and West Sacramento. No changes to traffic patterns on I Street or C Street would occur. The four approach structures would remain in place and in use; and there would be no changes to existing roadways, levees or Class I bikeways.

Improvements and development of transportation infrastructure would continue following the General Plans of both cities, the Sacramento Railyards Specific Plan (approved December 2007), and the Washington Specific Plan (adopted May 1996). The Sacramento Railyards Specific Plan identifies the extension of Railyards Boulevard west to a Tee intersection at Jibboom Street. Railyards Boulevard at Bercut Drive would consist of two westbound lanes and one eastbound lane. The same number of lanes on Railyards Boulevared would extend west to the intersection with Jibboom Street; at this point, the left westbound lane on Railyards

Boulevard would become a dedicated left-turn onto southbound Jibboom Street, and the right westbound lane would be a dedicated right-turn onto northbound Jibboom Street.

In West Sacramento, future changes to C Street would be based on the Washington Specific Plan, which identifies 12-foot-wide sidewalks and 7-foot-wide Class II bike lanes along the roadway. The connection to the I Street Bridge would not change.

2.4 Traffic Data

Emission estimations in this Air Quality Study Report are based on traffic data prepared specifically for the proposed project. **Tables 2-1** through **2-3** include regional VMT, local I Street Bridge traffic, truck percentages, truck volumes, and vehicle speeds for analysis years 2020 (Opening Year) and 2040 (Horizon Year). Results of the traffic report did not indicate operational differences between Build Alternatives. Regionally, VMT is identical for the Build Alternatives and emissions were estimated using one set of modeling criteria. Intersection LOS data is included in Appendix A.

Difference from No Build	--	--	27,180	(19,241)	--	(9,247)

/a/ For 2020 Build conditions, two different methods were used to estimate vehicle miles traveled. The first method is where the travel forecasting model trip assignment step is run in isolation. Under this method, all of the regional trip origins and destinations remain constant from the no build scenario. The only travel pattern change is the route that vehicle trips take between these origins and destinations since the short-term travel response to the bridge being opened is likely limited to route choices (i.e., individuals are not likely to change their work location because of short relocation of the bridge). Over a longer period of time, other travel behavior may change including destination locations and travel modes, which are represented by the full model run method. This full run likely overstates the level of travel change that would occur while assignment only run may not fully capture the full range of travel behavior effects. Hence, both estimates are provided and reviewers are cautioned to note that the modified Sacramento Regional Travel Demand Model (SACMET) used to generate these forecasts represents the entire six-county SACOG region and the network changes being made for this analysis are limited to a handful of links just a few 100 feet long.

3.0 AFFECTED ENVIRONMENT; ENVIRONMENTAL CONSEQUENCES; AND AVOIDANCE, MINIMIZATION, AND/OR MITIGATION MEASURES

3.1 Affected Environment

This section discusses federal and State laws and regulations, air quality standards and attainment designations, the physical setting, and environmental consequences.

3.1.1 Regulatory Setting

The FCAA, as amended, is the primary federal law that governs air quality while the California Clean Air Act (CCAA) is its companion state law. These laws, and related regulations by the U.S. Environmental Protection Agency (EPA) and the California Air Resources Board (CARB), set standards for the concentration of pollutants in the air. At the federal level, these standards are called National Ambient Air Quality Standards (NAAQS). NAAQS and the State level standards called California Ambient Air Quality Standards (CAAQS), have been established for six transportation-related criteria pollutants that have been linked to potential health concerns: CO, nitrogen dioxide (NO_2), ozone (O_3), particulate matter (PM), which is broken down for regulatory purposes into PM_{10} and $PM_{2.5}$, and sulfur dioxide (SO_2). In addition, federal and State standards exist for lead (Pb), and State standards exist for visibility reducing particles, sulfates, hydrogen sulfide, and vinyl chloride. The NAAQS and State standards are set at levels that protect public health with a margin of safety, and are subject to periodic review and revision. Both State and federal regulations also cover toxic air contaminants (air toxics); some criteria pollutants are also air toxics or may include certain air toxics in their general definition.

Air Quality

A combination of federal, State, and local laws and regulations govern air quality in the project area. The laws and regulations related to the relevant jurisdictions are discussed below.

Federal Air Quality Standards

Federal air quality standards and regulations provide the basic scheme for project-level air quality analysis under National Environmental Protection Agency (NEPA). In addition to this environmental analysis, a parallel conformity requirement under the FCAA also applies. The sections of FCAA directly applicable to the proposed project include Title I (Non-attainment Provisions) and Title II (Mobile Source Provisions). Title I requirements are implemented for the purpose of attaining NAAQS for the following criteria pollutants: (1) O_3, (2) NO_2, (3) SO_2, (4) PM_{10} and $PM_{2.5}$, (5) CO, and (6) Pb. The NAAQS are shown in **Table 3-1**. along with principal health effects, atmospheric effects, and sources of each criteria pollutant.

Title II of the FCAA pertains to mobile sources, such as cars, trucks, buses, and planes. Reformulated gasoline, automobile pollution control devices, and vapor recovery nozzles on gas pumps are a few mechanisms that U.S. EPA uses to regulate mobile air emission sources. The provisions of Title II resulted in tailpipe emission standards for vehicles, which have strengthened in recent years to improve air quality. For example, the standards for NO_2 emissions have been lowered substantially, and the specification requirements for cleaner burning gasoline have been made more stringent.

TABLE 3-1: STATE AND FEDERAL CRITERIA AIR POLLUTANT STANDARDS, EFFECTS, AND SOURCES

Pollutant	Averaging Time	State /i/ Standard	Federal /i/ Standard	Principal Health and Atmospheric Effects	Typical Sources
Ozone (O_3)/b/	1 hour 8 hours	0.09 ppm 0.070 ppm	--- /d/ 0.075 ppm (4th highest in 3 years)	High concentrations irritate lungs. Long-term exposure may cause lung tissue damage and cancer. Long-term exposure damages plant materials and reduces crop productivity. Precursor organic compounds include many known toxic air contaminants. Biogenic VOC may also contribute.	Low-altitude ozone is almost entirely formed from reactive organic gases/volatile organic compounds (ROG or VOC) and nitrogen oxides (NO_X) in the presence of sunlight and heat. Common precursor emitters include motor vehicles and other internal combustion engines, solvent evaporation, boilers, furnaces, and industrial processes.
Carbon Monoxide (CO)	1 hour 8 hours 8 hours (Lake Tahoe)	20 ppm 9.0 ppm /a/ 6 ppm	35 ppm 9 ppm ---	CO interferes with the transfer of oxygen to the blood and deprives sensitive tissues of oxygen. CO also is a minor precursor for photochemical ozone. Colorless, odorless.	Combustion sources, especially gasoline-powered engines and motor vehicles. CO is the traditional signature pollutant for on-road mobile sources at the local and neighborhood scale. :
Respirable Particulate Matter (PM_{10})/b/	24 hours Annual	50 µg/m^3 20 µg/m^3	150 µg/m^3 --- /b/ (expected number of days above standard < or equal to 1)	Irritates eyes and respiratory tract. Decreases lung capacity. Associated with increased cancer and mortality. Contributes to haze and reduced visibility. Includes some toxic air contaminants. Many toxic & other aerosol and solid compounds are part of PM_{10}.	Dust- and fume-producing industrial and agricultural operations; combustion smoke & vehicle exhaust; atmospheric chemical reactions; construction and other dust-producing activities; unpaved road dust and re-entrained paved road dust; natural sources.
Fine Particulate Matter ($PM_{2.5}$) /b/	24 hours Annual	--- 12 µg/m^3	35 µg/m^3 12.0 µg/m^3	Increases respiratory disease, lung damage, cancer, and premature death. Reduces visibility and produces surface soiling. Most diesel exhaust particulate matter – a toxic air contaminant – is in the $PM_{2.5}$ size range. Many toxic & other aerosol and solid compounds are part of $PM_{2.5}$.	Combustion including motor vehicles, other mobile sources, and industrial activities; residential and agricultural burning; also formed through atmospheric chemical and photochemical reactions involving other pollutants including NO_X, sulfur oxides (SO_x), ammonia, and ROG.

TABLE 3-1: STATE AND FEDERAL CRITERIA AIR POLLUTANT STANDARDS, EFFECTS, AND SOURCES

Pollutant	Averaging Time	State /i/ Standard	Federal /i/ Standard	Principal Health and Atmospheric Effects	Typical Sources
Nitrogen Dioxide (NO_2)	1 hour Annual	0.18 ppm 0.030 ppm	0.100 ppm /f/ (98^{th} percentile over 3 years) 0.053 ppm	Irritating to eyes and respiratory tract. Colors atmosphere reddish-brown. Contributes to acid rain & nitrate contamination of stormwater. Part of the "NO_x" group of ozone precursors.	Motor vehicles and other mobile or portable engines, especially diesel; refineries; industrial operations.
Sulfur Dioxide (SO_2)	1 hour 3 hours 24 hours	0.25 ppm --- 0.04 ppm	0.075 ppm /g/ (98^{th} percentile over 3 years) 0.5 ppm /g/ 0.14	Irritates respiratory tract; injures lung tissue. Can yellow plant leaves. Destructive to marble, iron, steel. Contributes to acid rain. Limits visibility.	Fuel combustion (especially coal and high-sulfur oil), chemical plants, sulfur recovery plants, metal processing; some natural sources like active volcanoes. Limited contribution possible from heavy-duty diesel vehicles if ultra-low sulfur fuel not used.
Lead (Pb)	Monthly Rolling 3-month average Calendar Quarter	1.5 µg/m^3 --- 	--- 0.15 µg/m^3 1.5 µg/m^3	Disturbs gastrointestinal system. Causes anemia, kidney disease, and neuromuscular and neurological dysfunction. Also a toxic air contaminant and water pollutant.	Lead-based industrial processes like battery production and smelters. Lead paint, leaded gasoline. Aerially deposited lead from older gasoline use may exist in soils along major roads.
Sulfate	24 hours	25 µg/m^3	---	Premature mortality and respiratory effects. Contributes to acid rain. Some toxic air contaminants attach to sulfate aerosol particles.	Industrial processes, refineries and oil fields, mines, natural sources like volcanic areas, salt-covered dry lakes, and large sulfide rock areas.
Hydrogen Sulfide (H_2S)	1 hour	0.03 ppm	---	Colorless, flammable, poisonous. Respiratory irritant. Neurological damage and premature death. Headache, nausea. Strong odor.	Industrial processes such as: refineries and oil fields, asphalt plants, livestock operations, sewage treatment plants, and mines. Some natural sources like volcanic areas and hot springs.
Visibility Reducing Particles (VRP)	8 hours	Visibility of 10 miles or more (Tahoe: 30 miles) at relative humidity less than 70%	---	Reduces visibility. Produces haze. NOTE: not directly related to the Regional Haze program under the Federal Clean Air Act, which is oriented primarily toward visibility issues in National Parks and other "Class I" areas. However, some issues and measurement methods are similar.	See particulate matter above. May be related more to aerosols than to solid particles.

TABLE 3-1: STATE AND FEDERAL CRITERIA AIR POLLUTANT STANDARDS, EFFECTS, AND SOURCES

Pollutant	Averaging Time	State /i/ Standard	Federal /i/ Standard	Principal Health and Atmospheric Effects	Typical Sources
Vinyl Chloride /c/	24 hours	0.01 ppm	---	Neurological effects, liver damage, cancer. Also considered a toxic air contaminant.	Industrial processes

Adapted from CARB Air Quality Standards chart (http://www.arb.ca.gov/research/aaqs/aaqs2.pdf).

Notes: ppm = parts per million; $\mu g/m^3$ = micrograms per cubic meter; ppb = parts per billion (thousand million); n/a = not applicable

/a/Rounding to an integer value is not allowed for the State 8-hour CO standard. A violation occurs at or above 9.05 ppm.
/b/Annual PM_{10} NAAQS revoked October 2006; was 50 $\mu g/m^3$. 24-hr. $PM_{2.5}$ NAAQS tightened October 2006; was 65 $\mu g/m^3$. Annual $PM_{2.5}$ NAAQS tightened from 15 $\mu g/m^3$ to 12 $\mu g/m^3$ December 2012 and secondary annual standard set at 15 $\mu g/m^3$.
/c/The CARB has identified vinyl chloride and the particulate matter fraction of diesel exhaust as toxic air contaminants. Diesel exhaust particulate matter is part of PM_{10} and, in larger proportion, $PM_{2.5}$.
/d/Both the CARB and U.S. EPA have identified lead and various organic compounds that are precursors to ozone and $PM_{2.5}$ as toxic air contaminants. There are no exposure criteria for adverse health effect due to toxic air contaminants, and control requirements may apply at ambient concentrations below any criteria levels specified above for these pollutants or the general categories of pollutants to which they belong.
/e/Prior to 6/2005, the 1-hour ozone NAAQS was 0.12 ppm. Emission budgets for 1-hour ozone are still be in use in some areas where 8-hour ozone emission budgets have not been developed, such as the S.F. Bay Area.
/f/The 65 $\mu g/m^3$ $PM_{2.5}$ (24-hour) NAAQS was not revoked when the 35 $\mu g/m^3$ NAAQS was promulgated in 2006. The 15 $\mu g/m^3$ annual $PM_{2.5}$ standard was not revoked when the 12 $\mu g/m^3$ standard was promulgated in 2012. The 0.08 ppm 1997 ozone standard is revoked FOR CONFORMITY PURPOSES ONLY when area designations for the 2008 0.75 ppm standard become effective for conformity use (7/20/2013). Conformity requirements apply for all NAAQS, including revoked NAAQS, until emission budgets for newer NAAQS are found adequate, SIP amendments for the newer NAAQS are approved with a emission budget, U.S. EPA specifically revokes conformity requirements for an older standard, or the area becomes attainment/unclassified. SIP-approved emission budgets remain in force indefinitely unless explicitly replaced or eliminated by a subsequent approved SIP amendment. During the "Interim" period prior to availability of emission budgets, conformity tests may include some combination of build vs. no build, build vs. baseline, or compliance with prior emission budgets for the same pollutant.
/g/Final 1-hour NO_2 NAAQS published in the Federal Register on 2/9/2010, effective 3/9/2010. Initial area designation for California (2012) was attainment/unclassifiable throughout. Project-level hot-spot analysis requirements do not currently exist. Near-road monitoring starting in 2013 may cause redesignation to nonattainment in some areas after 2016.
/h/U.S. EPA finalized a 1-hour SO_2 standard of 75 ppb in June 2010.
/i/State standards are "not to exceed" or "not to be equaled or exceeded" unless stated otherwise. Federal standards are "not to exceed more than once a year" or as described above.
/j/Secondary standard, set to protect public welfare rather than health. Conformity and environmental analysis address both primary and secondary NAAQS.

CAA Conformity Requirements for Transportation

The conformity requirement is based on FCAA Section 176(c), which prohibits the U.S. Department of Transportation (DOT) and other federal agencies from funding, authorizing, or approving plans, programs or projects that do not conform to State Implementation Plans (SIPs) for attainting the NAAQS. Transportation conformity applies to highway and transit projects and takes place on two levels: the regional—or, planning and programming level—and the project level. A proposed project must conform at both levels to be approved.

Conformity requirements apply only in nonattainment and maintenance (former nonattainment) areas for the NAAQS, and only for the specific NAAQS that are or were violated. U.S. EPA regulations at 40 CFR 93 govern the conformity process. Conformity requirements do not apply in unclassifiable/attainment areas for NAAQS and do not apply at all for State standards regardless of the status of the area.

Regional conformity is concerned with how well the regional transportation system supports plans for attaining the NAAQS for CO, NO_2, O_3, PM_{10}, and $PM_{2.5}$, and in some areas (although not in California), SO_2. California has attainment or maintenance areas for all of these transportation-related criteria pollutants except SO_2, and also has a nonattainment area for lead; however, lead is not currently required by the FCAA to be covered in a transportation conformity analysis. Regional conformity is based on the emission analysis of Regional Transportation Plans (RTPs) and Federal Transportation Improvement Programs (FTIPs) that include all transportation projects planned for a region over a period of at least 20 years for the RTP, and 4 years for the FTIP. The RTP and FTIP conformity use travel demand and emission models to determine whether or not the implementation of those projects would conform to emission budgets or other tests at various analysis years showing that requirements of the FCAA and the SIP are met. If the conformity analysis is successful, the Metropolitan Planning Organization (MPO), FHWA, and Federal Transit Administration (FTA), make determinations that the RTP and FTIP are in conformity with the SIP for achieving the goals of the FCAA. Otherwise, the projects in the RTP and/or FTIP must be modified until conformity is attained. If the design concept, scope, and "open-to-traffic" schedule of a proposed transportation project are the same as described in the RTP and FTIP, then the proposed project meets regional conformity requirements for purposes of a project-level analysis.

Conformity analysis at the project-level includes verification that the project is included in the regional conformity analysis and a "hot-spot" analysis if an area is "nonattainment" or "maintenance" for CO and/or particulate matter (PM_{10} or $PM_{2.5}$). A region is "nonattainment" if one or more of the monitoring stations in the region measure a violation of the relevant standard and the U.S. EPA officially designates the area nonattainment. Areas that were previously designated as nonattainment areas but subsequently meet the standard may be officially re-designated to attainment by the U.S. EPA, and are then called "maintenance" areas. A "hot-spot" analysis is essentially the same, for technical purposes, as a CO or particulate matter analysis performed for NEPA purposes. Conformity does include some specific procedural and documentation standards for projects that require a hot-spot analysis. In general, projects must not cause the "hot-spot"-related standard to be violated, and must not cause any increase in the number and severity of violations in nonattainment areas. If a known CO or particulate matter violation is located in the project vicinity, the project must include measures to reduce or eliminate the existing violation(s) as well.

State Air Quality Standards

Air quality in California is also regulations under the CCAA. In California, the CCAA is administered by CARB at the State level and by the air quality management districts and air pollution control districts at the regional and local levels. A major element of the CCAA is the requirement that local air districts which are in violation of the CAAQS must prepare air quality management or attainment plans that identify air quality problems, causes, trends and actions to be taken to attain and maintain California's air quality standards by the earliest practicable date. The CAAQS are shown in **Table 3-1**, above.

Local and Regional Implementation of Federal and State Requirements

In the project area, the regulation of air quality on the east side of the Sacramento River is under the jurisdiction of the SMAQMD. The regulation of air quality on the west side of the Sacramento River is under the jurisdiction of the YSAQMD. In addition, the SACOG is responsible for ensuring that transportation projects and plans do not impede the region's clean air goals.

Sacramento Metropolitan Air Quality Management District (SMAQMD)

The SMAQMD operates at the local level with primary responsibility for attaining and maintaining the federal and State ambient air quality standards in Sacramento County. The SMAQMD works jointly with U.S. EPA, CARB, SACOG, other air districts in the Sacramento region, county and city transportation and planning departments, and various non-governmental organizations to improve air quality through a variety of programs. These programs include the adoption of regulations, policies and guidance, extensive education and public outreach programs, as well as emission reducing incentive programs.

The SMAQMD developed the California Environmental Quality Act (CEQA) Guide to Air Quality Assessment to provide methods for the analysis and review of air quality impacts from land use development projects.[1] The primary purpose of the CEQA Guide is to provide useful tools to quickly identify proposed development projects that may have a significant adverse effect on air quality. This document includes screening approaches and specific methods for calculating emissions, with references to applicable models. This document also provides mitigation strategies developers can integrate into their projects to reduce air quality impacts. Significance thresholds to assess potential impacts for projects undergoing CEQA review are shown in **Table 3-2**.

Yolo-Solano Air Quality Management District (YSAQMD)

The YSAQMD is responsible for protecting human health and property from the harmful effects of air pollution. Established in 1971 by a joint powers agreement between the Yolo and Solano County boards of supervisors, the YSAQMD is governed by an air quality management board composed of representatives from both the County Boards of Supervisors and Mayors/City council members from the cities within the District. YSAQMD has jurisdiction over all of Yolo County and the northeast portion of Solano County, from Vacaville on the west, to Rio Vista on the south.

[1]SMAQMD, *CEQA Guide to Air Quality Assessment*, Revised November 2014.

TABLE 3-2: SMAQMD THRESHOLDS OF SIGNIFICANCE		
	Construction Phase	**Operational Phase**
ALL PROJECTS SUBJECT TO CEQA		
Mass Emission Thresholds		
NOx (ozone precursor)	85 pounds/day	65 pounds/day
ROG (VOC) (ozone precursor)	NONE	65 pounds/day
PM_{10}	Zero (0). If all feasible BACT/BMPs are applied, then 80 pounds/day and 14.6 tons/year	Zero (0). If all feasible BACT/BMPs are applied, then 80 pounds/day and 14.6 tons/year
$PM_{2.5}$	Zero (0). If all feasible BACT/BMPs are applied, then 82 pounds/day and 15 tons/year	Zero (0). If all feasible BACT/BMPs are applied, then 82 pounds/day and 15 tons/year
LAND DEVELOPMENT AND CONSTRUCTION PROJECTS		
Greenhouse Gas Emissions (GHG) Thresholds		
GHG as CO2e	1,100 metric tons/year	10,000 metric tons/year

NOTES:
The SMAQMD Board of Directors adopted air quality thresholds of significance for criteria pollutants on March 28, 2002, via resolution AQMD2002018. Official
The SMAQMD Board of Directors adopted GHG thresholds on October 23, 2014, via resolution AQMD2014-028
GHG operational emissions in excess of 1,100 metric ton/year must be reduced to 1,100 metric tons or by 21.7 percent relative to the No Action Taken scenario.
SOURCE: SMAQMD, *CEQA Guide to Air Quality Assessment*, Revised November 2014.

The YSAQMD prepared the Handbook for Assessing and Mitigating Air Quality Impacts as an advisory document to provide Lead Agencies, consultants, and project applicants with procedures for addressing air quality impacts in environmental documents.[2] The Handbook contains the following components:

- Preliminary actions Lead Agencies can take to reduce air quality impacts prior to beginning the CEQA process;
- Criteria and thresholds for determining whether a project may have a significant adverse air quality impact;
- Project screening methods, specific procedures and modeling protocols for quantifying and analyzing air quality impacts; and
- Measures that can be implemented to mitigate air quality impacts.

The YSAQMD quantitative significance thresholds are shown in **Table 3-3**. The thresholds apply to construction and operational impacts. The YSAQMD was part of the working group that developed the draft regional GHG thresholds for the Sacramento area, which SMAQMD adopted and are shown in **Table 3-2**. Accordingly, YSAQMD has draft thresholds that are consistent with what is shown in **Table 3-2** for SMAQMD, but have not been formally adopted.

[2]YSAQMD, *Handbook for Assessing and Mitigating Air Quality Impacts*, July 11, 2007.

TABLE 3-3: YSAQMD THRESHOLDS OF SIGNIFICANCE FOR CRITERIA POLLUTANTS OF CONCERN

Pollutant	Thresholds of Significance
ROG	10 tons per year
NO_X	10 tons per year
PM_{10}	80 pounds per day
CO	Violation of a State Ambient Air Quality Standard for CO

SOURCE: YSAQMD, *Handbook for Assessing and Mitigating Air Quality Impacts*, July 11, 2007.

Sacramento Area Council of Governments (SACOG)

The SACOG is an association of local governments in the six-county Sacramento Region. Members include the Counties of El Dorado, Placer, Sacramento, Sutter, Yolo and Yuba as well as 22 cities. The SACOG provides transportation planning and funding for the region, and serves as a forum for the study and resolution of regional issues. In addition to preparing the region's Long-Range Transportation Plan, SACOG approves the distribution of affordable housing in the region and assists in planning for transit, bicycle networks, clean air and airport land uses.

SACOG prepared the FTIP and MTP/SCS. The FTIP is known as the Metropolitan Transportation Improvement Program (MTIP) in the Sacramento Region. It is a short-term listing of surface transportation projects that: receive federal funds, are subject to a federally required action, or are regionally significant. Apart from some improvements to the region's airports and the Port of Sacramento, all regionally significant transportation projects and federally funded capital projects are part of the MTIP. This means that many-but not all-transit, highway, local roadway, bicycle and pedestrian investments are included in the MTIP. SACOG, as the federally designated MPO for the six-county Sacramento Region, prepares and adopts the MTIP every two years.

Only projects included in the MTP/SCS may be incorporated into the MTIP. The MTIP derives all its projects either directly from the MTP/SCS or indirectly from the policies within it. The MTP/SCS is the long range policy and planning document while the MTIP is the short range implementing document that enables those planned project to begin work. Specifically, the MTIP lists those projects from the MTP/SCS that have committed or reasonably available funding and intend to begin a phase of work during the four years of the MTIP.

3.1.2 Physical Setting

Climate and Topography

The following climate and topography discussion was included in the Conformity Analysis for the 2015/2018 MTIP.[3] The Sacramento Valley is a basin bounded by the Sierra Nevada Mountain Range to the east and the Coastal Mountain Ranges to the west. Topography in the Sacramento Valley is generally flat, with elevations anywhere from slightly below sea level near the Sacramento/San Joaquin Delta to over 2,150 feet above sea level at the Sutter Buttes. Hot dry summers and mild rainy winters characterize the Mediterranean climate of the Sacramento Valley Air Basin (SVAB). During the year the temperature may range from 20 to 115 degrees Fahrenheit with summer highs usually in the 90s and winter lows occasionally below freezing. Average annual rainfall is about 20 inches with about 75 percent occurring during the rainy

[3]SACOG, *Conformity Analysis for the 2015/18 Metropolitan Transportation Improvement Program and Amendment #4 to the Metropolitan Transportation Plan and Sustainable Communities Strategy 2035*, adopted September 2014.

season generally from November through March. The prevailing winds are moderate in strength and vary from moist clean breezes from the south to dry land flows from the north.

The mountains surrounding the SVAB create a barrier to airflow, which can trap air pollutants when certain meteorological conditions exist. The highest frequency of air stagnation occurs in the autumn and early winter when large high-pressure cells lie over the Sacramento Valley. The lack of surface wind during these periods and the reduced vertical flow caused by less surface heating reduces the influx of outside air and allows air pollutants to become concentrated in a stable volume of air. The surface concentrations of particulate matter pollutants are highest when these conditions are combined with smoke or when temperature inversions trap cool air, fog and pollutants near the ground.

The ozone season (May through October) in the Sacramento Valley is characterized by stagnant morning air or light winds, with the delta sea breeze arriving in the afternoon out of the southwest.

In addition, longer daylight hours provide a plentiful amount of sunlight to fuel photochemical reactions between ROG and NOx, which result in ozone formation. Likewise, $PM_{2.5}$ peak concentrations typically occur during the winter season (November – February) when temperature inversion and low wind speeds trap and concentrate $PM_{2.5}$ emissions, cooler temperature and high humidity increase the secondary formation of particulates.

As an air basin, air quality in the Sacramento region is impacted not only by pollutants generated within the region, but also by pollutants generated in the San Francisco Bay Area and the San Joaquin Valley, which are carried into the Sacramento region by Delta breezes. The effect of pollutants transported from the San Francisco Bay Area or from the San Joaquin Valley on air quality in the Sacramento region can vary from substantial to inconsequential on any given day, largely determined by accompanying meteorological conditions. Thus, the success of the Sacramento region in attaining better air quality is partially contingent on the achievement of better air quality in nearby areas that affect Sacramento's air quality.

Description of NAAQS AND CAAQS Pollutants

The primary pollutants of concern in the project area are O_3 and its precursors, reactive organic gases (ROG) and NO_X, as well as CO, PM_{10}, and $PM_{2.5}$. O_3, PM_{10}, and $PM_{2.5}$ are considered to be regional pollutants because they affect air quality on a regional scale. NO_2 reacts photo-chemically with ROG to form O_3, while PM_{10} and $PM_{2.5}$ can form from chemical reaction of atmospheric chemicals, including NO_X, sulfates, nitrates, and ammonia. These processes can occur at some distance downwind of the source of pollutants. Pollutants, such as CO, are considered to be local pollutants because they tend to disperse rapidly with distance from the source. Although PM_{10} and $PM_{2.5}$ are regional pollutants, they can also be localized pollutants, as direct emissions of PM_{10} from automobile exhaust can accumulate in the air locally near the emission source.

The following is a brief overview of O_3, CO, PM_{10}, and $PM_{2.5}$. MSAT and CO_2 are also discussed, even though there are currently no adopted standards to control these pollutants.

Ozone

O_3 is a respiratory irritant that increases susceptibility to respiratory infections. It is also an oxidant that can cause substantial damage to vegetation and other materials. O_3 is not emitted directly into the air but is formed by a photochemical reaction in the atmosphere. The O_3

precursors ROG and NO_X react in the atmosphere in the presence of sunlight to form O_3. Because photochemical reaction rates depend on the intensity of ultraviolet light and air temperature, O_3 pollution is primarily a problem in the summer.

Carbon Monoxide

CO is a public health concern because it combines readily with hemoglobin and reduces the amount of oxygen transported in the bloodstream. CO can cause health problems such as fatigue, headache, confusion, dizziness, and even death. Motor vehicles are the dominant source of CO emissions in most areas. High CO levels develop primarily during winter when periods of light winds combine with the formation of ground-level temperature inversions (typically from the evening through early morning). These conditions result in reduced dispersion of vehicle emissions. Motor vehicles also exhibit increased CO emission rates at low air temperatures.
Inhalable Particulate Matter

Particulate matter pollution consists of very small liquid and solid particles floating in the air, which can include smoke, soot, dust, salts, acids, and metals. Particulate matter also forms when gases emitted from industries and motor vehicles undergo chemical reactions in the atmosphere. Particulate matter less than 10 microns in diameter, about 1/7th the thickness of a human hair, is referred to as PM_{10}. Particulate matter that is 2.5 microns or less in diameter, roughly 1/28th the diameter of a human hair, is referred to as $PM_{2.5}$. Major sources of PM_{10} include motor vehicles; wood burning stoves and fireplaces; dust from construction, landfills, and agriculture; wildfires and brush/waste burning; industrial sources; windblown dust from open lands; and atmospheric chemical and photochemical reactions. $PM_{2.5}$ results from fuel combustion (from motor vehicles, power generation, and industrial facilities), residential fireplaces, and wood stoves. In addition, PM_{10} and $PM_{2.5}$ can be formed in the atmosphere from gases such as SO_2, NO_X, and ROG.

PM_{10} and $PM_{2.5}$ pose a greater health risk than larger-size particles. When inhaled, these tiny particles can penetrate the human respiratory system's natural defenses and damage the respiratory tract. PM_{10} and $PM_{2.5}$ can increase the number and severity of asthma attacks, cause or aggravate bronchitis and other lung diseases, and reduce the body's ability to fight infections. Very small particles of substances, such as lead, sulfates, and nitrates, can cause lung damage directly. These substances can be absorbed into the blood stream and cause damage elsewhere in the body; they can also transport absorbed gases such as chlorides or ammonium into the lungs and cause injury. Whereas particles 2.5 to 10 microns in diameter tend to collect in the upper portion of the respiratory system, particles 2.5 microns or less are so tiny that they can penetrate deeper into the lungs and damage lung tissues. Suspended particulates also damage and discolor surfaces on which they settle, and contribute to haze and reduce regional visibility.

Lead

As a result of regulatory efforts to reduce the content of Pb in gasoline, the contribution of Pb from the transportation sector has been substantially reduced. Industrial activities are the major source of Pb emissions to the atmosphere. CARB reports the effects from inhalation of Pb include impaired blood formation and nerve conduction. Pb can adversely affect the nervous, reproductive, digestive, immune, and blood-forming systems. Symptoms can include fatigue, anxiety, short-term memory loss, depression, weakness in the extremities, and learning disabilities in children. Pb also causes cancer.

Toxic Air Contaminants/Mobile Source Air Toxics

Toxic air contaminants (TACs) are pollutants that may result in an increase in mortality or serious illness or that may pose a present or potential hazard to human health. Health effects of TACs include cancer, birth defects, neurological damage, damage to the body's natural defense system, and diseases that lead to death. In 1998, following a 10-year scientific assessment process, CARB identified particulate matter from diesel-fueled engines as a TAC. Compared to other air toxics that CARB has identified and controlled, diesel particulate matter emissions are estimated to be responsible for about 70 percent of the total ambient air toxics risk.[4]

The CCAA made controlling air toxic emissions a national priority, by which Congress mandated that U.S. EPA regulate 188 air toxics. These substances are also known as hazardous air pollutants. In U.S. EPA's latest rule, Control of Emissions of Hazardous Air Pollutants from Mobile Sources (Federal Registry, Vol. 72, No. 37, page 8430, February 2007), it identified a group of 93 compounds emitted from mobile sources that are listed in its Integrated Risk Information System (IRIS). The IRIS is a comprehensive database of specific substances known to cause human health effects. In addition, U.S. EPA identified the following seven compounds as priority MSATs.

- Acrolein
- Benzene
- 1,3-Butadiene
- Diesel particulate matter/diesel exhaust organic gases
- Formaldehyde
- Naphthalene
- Polycyclic organic matter

While FHWA considers these the priority MSATs, the list is subject to change and may be adjusted in consideration of future rules. To address emissions of MSATs, U.S. EPA has issued a number of regulations, including the 2007 rule mentioned above, that will dramatically decrease MSATs through cleaner fuels and cleaner engines.

The issue of air toxics is an emerging area of analysis and continuing research. Although much work has been done to assess the overall health risk of air toxics, many questions remain unanswered. In particular, the tools and techniques available for assessing project-specific health impacts from MSATs are currently limited. Given the emerging state of the science and of project-level analysis techniques, there are no established criteria for determining when MSAT emissions should be considered a significant issue in the context of NEPA.

FHWA released guidance for factoring mobile source health risks into project-level decision making under NEPA in December 2012.[5] However, U.S. EPA has not established regulatory concentration targets for the seven relevant MSAT pollutants appropriate for use in the project development process. The FHWA recommends MSAT analyses to be conducted using U.S. EPA's latest version of Motor Vehicle Emissions Simulator (MOVES) model, released on October 30, 2012, which estimates on- and off-road MSAT emissions from motor vehicles. FHWA's guidance advises the assessment of MSATs in NEPA documents.[6]

[6]*Ibid*.

Greenhouse Gases

The warming trend of the earth's atmosphere, also known as climate change, is related to the release of GHG into the atmosphere. The GHGs of main concern are carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O). Changes in climate may lead to sea level rise and changes to agriculture production, water supply, ecosystem sustainability and weather patterns. Increases in wildland fires and more extreme heat days leading to ozone formation have direct impacts to air quality in Sacramento County.

Existing Air Quality Conditions

The monitoring station closest to the project area is within the SMAQMD's jurisdiction. The Sacramento T Street Monitoring Station is located approximately 1.4 miles to the southeast (**Figure 3-1**). **Table 3-4** includes pollutant levels, the State and federal standards, and the number of exceedances recorded at the Sacramento T Street Monitoring Station. No standards were exceeded for CO, NO_2, or SO_2 between 2011 and 2014. The Federal 8-hour O_3 standard was was exceeded between 0 and 9 times annually, and the State 8-hour O_3 standard was exceeded 1 time in 2011 and 4 times in 2012. The State one-hour O_3 standard was exceeded 1 time in 2011 and 2012. The Federal PM_{10} and $PM_{2.5}$ standards were not exceeded between 2011 and 2014. The State 24-hour PM_{10} standard was exceeded 21 times in 2013 and 4 times in 2014. The State 24-hour $PM_{2.5}$ standard was exceeded 6 times in 2011 and 2 times in 2013.

Attainment Status

In the project area, the regulation of air quality on the east side of the Sacramento River is under the jurisdiction of SMAQMD. The U.S. EPA designates Sacramento County as nonattainment for O_3, $PM_{2.5}$, unclassified/attainment for Pb and NO_2, and maintenance for PM_{10} and CO.[7] The regulation of air quality on the west side of the Sacramento River is under the jurisdiction of YSAQMD. The U.S. EPA designates Yolo County as nonattainment for O_3, $PM_{2.5}$, unclassified/attainment for PM_{10}, Pb and NO_2, and maintenance for CO.[8] The conformity process does not address pollutants for which the area is attainment/unclassified, MSATs, other toxic air contaminants or hazardous air pollutants, or GHGs.

In accordance with the CCAA, CARB designates Sacramento and Yolo Counties as nonattainment for O_3, PM_{10}, and $PM_{2.5}$, attainment for CO, NO_2, SO_2, Pb, and sulfates, and unclassified for hydrogen sulfide and visibility reducing particles.[9]

Sensitive Receptors

Some land uses are considered more sensitive to changes in air quality than others, depending on the population groups and the activities involved. According to CARB, sensitive individuals refer to those segments of the population most susceptible to poor air quality (i.e., children, the elderly, and those with pre-existing serious health problems affected by air quality).[10] Land uses where sensitive individuals are most likely to spend time include schools and schoolyards, parks and playgrounds, daycare centers, nursing homes, hospitals, and residential communities. convalescent centers, and retirement homes. **Figure 3-2** shows sensitive receptors within 500 feet of the project site.

SENSITIVE RECEPTORS

3.2 Environmental Consequences

This section examines the degree to which the project alternatives may cause adverse or significant changes to air quality. Both short-term construction emissions and long-term effects related to the ongoing operation of the alternatives are discussed in this section.

3.2.1Transportation Conformity

The conformity requirement is based on FCAA Section 176(c), which prohibits the U.S. DOT and other federal agencies from funding, authorizing, or approving plans, programs or projects that do not conform to the SIP for attainting the NAAQS. The proposed project is exempt from all Transportation Conformity requirements per 40 CFR 93.126. The specific exemption is related to widening narrow pavements or reconstructing bridges without additional travel lanes. SACOG confirmed this finding on August 23, 2016.

3.2.2 Regional Emissions - Mobile Sources

Regional emissions were estimated using emission factors from the CARB EMFAC2014 model.[11] The traffic data for existing conditions was generated from a modified version of the 2008 base year SACMET model. Due to the 2008/09 recession, these results also describe 2013/2014 conditions. The region's loss of employment led to a decrease in travel activity after 2009 and traffic counts conducted for the City of Sacramento General Plan revealed that 2008 traffic levels had not rebounded fully by 2012. More recent 2013 and 2014 counts are similar to those from 2008 so there is evidence to support the base year model estimates as also representing 2014 conditions for this project. Existing emissions are greater than future emissions for all pollutants included in the analysis. Emission decreases from existing conditions to future years are due to improvements in engine efficiencies in addition to more advanced emission control technologies.

For 2020 Build Alternative conditions, two different methods were used to estimate vehicle miles traveled. The first method is where the travel forecasting model trip assignment step is run in isolation. Under this method, all of the regional trip origins and destinations remain constant from the no build scenario. The only travel pattern change is the route that vehicle trips take between these origins and destinations since the short-term travel response to the bridge being opened is likely limited to route choices (i.e., individuals are not likely to change their work location because of short relocation of the bridge). Over a longer period of time, other travel behavior may change including destination locations and travel modes, which are represented by the full model run method. This full run likely overstates the level of travel change that would occur while the assignment only run may not fully capture the full range of travel behavior effects. Both VMT and related emissions estimates are provided in this analysis. Reviewers are cautioned to note that the modified SACMET model used to generate these forecasts represents the entire six-county SACOG region and the network changes being made for this analysis are limited to a handful of links just a few hundred feet long. The VMT for both methods is show in **Table 2-1**, above.

Table 3-5 shows regional emissions for 2014 existing conditions and in 2020 and 2040 for the No Build and Build Alternatives. The emissions analysis indicates 2020 Build Alternative would generally result in a negligible change compared to the No Build Alternative. Pollutant emissions would decrease for most pollutants, except particulate matter. Despite decreased exhaust emissions, particulate matter emissions would increase in certain conditions due to re-entrained

[11]EMFAC2014 was released on December 30, 2014 by the CARB.

dust, break wear, and tire wear emissions. These emissions VMT would be directly correlated to the regional VMT relationship between the alternatives.

Because Caltrans has Statewide jurisdiction and the setting for projects varies so extensively across the State, Caltrans has not and will not develop thresholds of significance for CEQA. Further, because most air district thresholds have not been established by regulation or by delegation from a federal or State agency with regulatory authority over Caltrans, Caltrans is not required to adopt those thresholds in Caltrans' documents. Nevertheless, SMAQMD and YSAQMD thresholds of significance are provided for reference.

3.2.3 Mobile Source Air Toxics

Background

Controlling Air Toxic Emissions became a national priority with the passage of the FCAA Amendment of 1990, whereby Congress mandated that the U.S. EPA regulate 188 air toxics, also known as hazardous air pollutants. The U.S. EPA has assessed this expansive list in their latest rule on the Control of Hazardous Air Pollutants from Mobile Sources (Federal Register, Volume 72, No. 37, page 8430, February 26, 2007), and identified a group of 93 compounds emitted from mobile sources that are listed in their IRIS. In addition, the U.S. EPA identified seven compounds with significant contributions from mobile sources that are among the national and regional-scale cancer risk drivers from their 1999 National Air Toxics Assessment (NATA). These are acrolein, benzene, 1,3-butadiene, diesel particulate matter plus diesel exhaust organic gases (diesel PM), formaldehyde, naphthalene, and polycyclic organic matter. While FHWA considers these priority mobile source air toxics, the list is subject to change and may be adjusted in consideration of future U.S. EPA rules. The 2007 U.S. EPA rule mentioned above requires controls that will dramatically decrease MSAT emissions through cleaner fuels and cleaner engines.

Motor Vehicle Emissions Simulator

According to the U.S. EPA, MOVES improves upon the previous MOBILE model in several key aspects: MOVES is based on a vast amount of in-use vehicle data collected and analyzed since the latest release of MOBILE, including millions of emissions measurements from light-duty vehicles. Analysis of this data enhanced the U.S. EPA's understanding of how mobile sources contribute to emissions inventories and the relative effectiveness of various control strategies. In addition, MOVES accounts for the significant effects that vehicle speed and temperature have on PM emissions estimates, whereas MOBILE did not. MOVES2010b includes all air toxic pollutants in the NATA that are emitted by mobile sources. The U.S. EPA has incorporated more recent data into MOVES2010b to update and enhance the quality of MSAT emission estimates. This data reflects advanced emission control technology and modern fuels, plus additional data for older technology vehicles. Based on an FHWA analysis using U.S. EPA's MOVES2010b model, **Figure 3-3** shows that even if VMT increases by 102 percent as assumed from 2010 to 2050, a combined reduction of 83 percent in the total annual emissions for the priority MSAT is projected for the same time period.

The implications of MOVES on MSAT emissions estimates compared to MOBILE are: lower estimates of total MSAT emissions; significantly lower benzene emissions; significantly higher diesel PM emissions, especially for lower speeds. Consequently, diesel PM is projected to be the dominant component of the emissions total.

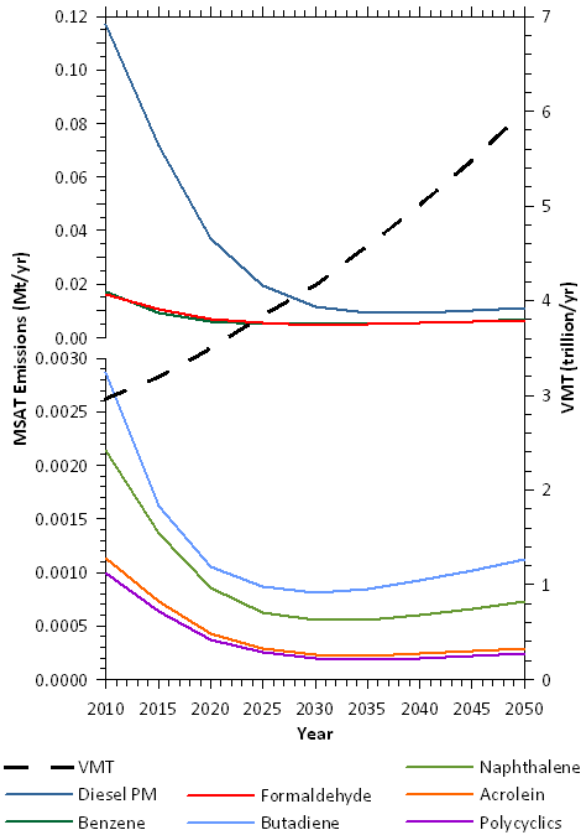

Figure 3-3. National MSAT Emission Trends 1999 – 2050 for Vehicles Operating on Roadways using U.S. EPA's MOVES2010b Model

Mobile Source Air Toxic Research

Air Toxics Analysis is a continuing area of research. While much work has been done to assess the overall health risk of air toxics, many questions remain unanswered. In particular, the tools and techniques for assessing project-specific health outcomes as a result of lifetime MSAT exposure remain limited. These limitations impede the ability to evaluate how potential public health risks posed by MSAT exposure should be factored into project-level decision-making within the context of NEPA.

Nonetheless, air toxics concerns continue to be raised on highway projects during the NEPA process. Even as the science emerges, the public and other agencies expect MSAT impacts to be addressed in environmental documents. The FHWA, U.S. EPA, the Health Effects Institute (HEI), and others have funded and conducted research studies to try to more clearly define potential risks from MSAT emissions associated with highway projects. The FHWA will continue to monitor the developing research in this field.

Mobile Source Air Toxic Emissions Analysis Designation

The FHWA, in its Interim Guidance published on December 6, 2012 (Interim Guidance on Mobile Source Air Toxic Analysis in NEPA Documents), recommends a range of options deemed appropriate for addressing and documenting the MSAT in NEPA documents.

1. No analysis for exempt projects or projects that have no potential for meaningful MSAT effects.

2. Qualitative analysis for projects with low potential MSAT effects.

3. Quantitative analysis to differentiate alternatives for projects with higher potential MSAT effects.

Exempt Projects or Projects with No Meaningful Potential MSAT Effects

The types of projects included in this category—those that are exempt of have no meaningful potential MSAT effects—are listed below.

- Projects qualifying as a categorical exclusion under 23 CFR 771.117(c).
- Projects exempt under the CAA Conformity Rule under 40 CFR 93.126.
- Other projects with no meaningful impacts on traffic volumes or vehicle mix.

For projects that are categorically excluded under 23 CFR 771.117(c), or are exempt from all conformity requirements under the FCAA pursuant to 40 CFR 93.126, no analysis or discussion of MSAT is necessary. Documentation sufficient to demonstrate that the project qualifies as a categorical exclusion and/or exempt project will suffice. For other projects with no or negligible traffic impacts, regardless of the class of NEPA environmental document, no MSAT analysis is recommended.[12] However, the project record should document the basis for the determination of "no meaningful potential impacts" with a brief description of the factors considered.

Projects with Low Potential MSAT Effects

The types of projects included in this category—projects with low potential MSAT effects—are those that serve to improve operations of highway, transit, or freight without adding substantial new capacity or without creating a facility that is likely to meaningfully increase MSAT emissions. This category covers a broad range of projects.

FHWA anticipates that most highway projects that need an MSAT assessment will fall into this category. Any projects not meeting the criteria for exempt projects/projects without meaningful potential effects (discussed above) or projects with higher potential MSAT effects (discussed below) should be included in this category. Examples of these types of projects are minor widening projects, new interchanges, replacing a signalized intersection on a surface street, or projects where design year traffic is projected to be less than 140,000 to 150,000 AADT.

For these projects, a qualitative assessment of emissions projections should be conducted. This qualitative assessment would compare, in narrative form, the expected effect of the project on traffic volumes, vehicle mix, or routing of traffic and the associated changes in MSAT for the project alternatives, including the No Build Alternative, based on VMT, vehicle mix, and speed. It would also discuss national trend data projecting substantial overall reductions in emissions due to stricter engine and fuel regulations issued by U.S. EPA. Because the emission effects of these projects typically are low, we expect there would be no appreciable difference in overall MSAT emissions among the various alternatives.

[12]The types of projects categorically excluded under 23 CFR 771.117(d) or exempt from certain conformity requirements under 40 CFR 93.127 does not warrant an automatic exemption from an MSAT analysis, but they usually will have no meaningful impact.

Projects with Higher Potential MSAT Effects

This category includes projects that have the potential for meaningful differences in MSAT emissions among project alternatives. It is expected a limited number of projects would meet the criteria to fall into this category, which are as follows.

- Projects that create or significantly alter a major intermodal freight facility that has the potential to concentrate high levels of DPM in a single location, involving a significant number of diesel vehicles for new projects or accommodating with a significant increase in the number of diesel vehicles for expansion projects; or

- Projects that create new capacity or add significant capacity to urban highways, such as interstates, urban arterials, or urban collector-distributor routes with traffic volumes where the AADT is projected to be in the range of 140,000 to 150,000, or greater, by the design year.

- Projects that are proposed to be located in proximity to populated areas.

Projects falling within this category should be more rigorously assessed for impacts, including a quantitative analysis to forecast local-specific emission trends of the priority MSAT for each alternative. Based on regulations now in effect, an analysis of national trends with EPA's MOVES model, as shown in **Figure 3-3**, even if VMT increases by 102 percent as assumed from 2010 to 2050, a combined reduction of 83 percent in the total annual emissions for the priority MSAT is projected for the same time period.

Mobile Source Air Toxic Emissions in the Project Area

The proposed project is not exempt from an MSAT analysis and the 2040 ADT of 33,030 would be less than the screening guidance of 140,000. Based on the FHWA guidance, the proposed project has low potential for meaningful differences in MSAT emissions among project alternatives (Level 2 Analysis). A qualitative analysis is identified as the appropriate analysis. For each alternative, the amount of MSAT emitted would be proportional to the VMT, assuming that other variables such as fleet mix are the same for each alternative. The VMT estimated for each of the Build Alternatives is slightly higher than that for the No Build Alternative, because the proposed project facilitates new development, attracting trips that would not otherwise occur in the area. This increase in VMT means MSAT under the Build Alternatives would probably be higher than the No Build Alternative in the project area. There could also be localized differences in MSAT from the indirect effects of the project, such as associated access traffic, emissions of evaporative MSAT (e.g., benzene) from parked cars, and emissions of diesel PM from delivery trucks (modified depending on the type and extent of the associated development). Travel to other destinations would be reduced with subsequent decreases in emissions at those locations.

Because the estimated regional VMT under each of the Build Alternatives are nearly the same, increasing by approximately 0.1 percent in 2020 and decreasing by approximately 0.1 in 2040, it is expected there would be no appreciable difference in overall MSAT emissions between the No Build and Alternative and Build Alternatives. In addition, there is a negligible difference in 2020 regional emissions between the full and assignment-only VMT model runs. For all Alternatives, emissions are virtually certain to be lower than present levels in the design year as a result of U.S. EPA's national control programs that are projected to reduce annual MSAT emissions by over 80 percent from 2010 to 2050. Local conditions may differ from these national projections in terms of fleet mix and turnover, VMT growth rates, and local control

measures. However, the magnitude of the U.S. EPA-projected reductions is so great (even after accounting for VMT growth) that MSAT emissions in the project area are likely to be lower in the future than they are today.

The travel lanes contemplated as part of the Build Alternatives will have the effect of moving some traffic closer to nearby homes, schools and businesses; therefore, under each Build Alternative there may be localized areas where ambient concentrations of MSAT would be higher under certain Alternatives than others. The localized differences in MSAT concentrations would likely be most pronounced along the new/expanded roadway sections that would be built at the bridge touchdown locations. However, the magnitude and the duration of these potential increases cannot be reliably quantified due to incomplete or unavailable information in forecasting project-specific MSAT health impacts. Further, under all Alternatives, overall future MSAT are expected to be substantially lower than today due to implementation of U.S. EPA's vehicle and fuel regulations.

In sum, there would be no appreciable difference in overall MSAT emissions among the various Build Alternatives. There could be increases in MSAT levels in a few localized areas where VMT increases. However, the U.S. EPA's vehicle and fuel regulations will bring about significantly lower MSAT levels for the area in the future than today.

3.2.4 Diesel Particulate Matter

In 1998, California identified diesel PM as a toxic air contaminant based on its potential to cause cancer, premature death, and other health problems. This assessment formed the basis for a decision by CARB to formally identify particles in diesel exhaust as a toxic air contaminant that may pose a threat to human health.

Diesel engines emit a complex mix of pollutants, the most visible of which are very small carbon particles or soot, known as diesel PM. Diesel exhaust also contains more than 40 cancer-causing substances, most of which are readily adsorbed on the soot particles. These include many known or suspected cancer-causing substances, such as benzene, arsenic, and formaldehyde.[13]

Overall, diesel engine emissions are responsible for most of California's estimated cancer risk attributable to air pollution. In addition, diesel PM is a significant fraction of California's particulate pollution problem.

CARB has found that diesel PM contributes more than 70 percent of the known risk from air toxics and poses the greatest cancer risks among all identified air toxics.[14] Diesel trucks contribute more than half of the total diesel combustion sources; however, CARB has adopted a Diesel Risk Reduction Plan with control measures that would reduce the overall diesel PM emissions by approximately 85 percent from 2000 to 2020.[15] In addition, the total toxic risk from diesel exhaust may be exposed for a much shorter duration. Furthermore, diesel PM is only one of many environmental toxics, and those other toxics and other pollutants in various environmental media may overshadow its cancer risks; therefore, while diesel exhaust may pose potential cancer risks to receptors spending time on or near high-risk diesel PM facilities, most receptors' short-term exposure would cause minimal harm, and these risks would also

[13] Air Quality and Diesel Emissions, Environmental Considerations, Office of Freight Planning, California Department of Transportation, website: http://www.dot.ca.gov/hq/tpp/offices/ogm/environment.html, accessed June 11, 2015.

[14] CARB, *Risk Reduction Plan to Reduce Particulate Matter Emissions from Diesel-Fueled Engines and Vehicles*, October 2000.

[15] *Ibid*.

greatly diminish in the future operating years of the proposed project due to planned emission control regulations.

In addition to diesel PM, ultrafine particles counts are highest near mobile sources, with some of the highest concentrations observed on busy roads. In the urban environment, motor vehicles are a major source of ultrafine particulates. Other recent studies have shown high counts of ultrafine particulates near freeways. While information on health effects of ultrafine particles is limited, various studies suggest that ultrafine particles may have significant health effects that are greater than or independent of the effects due to larger particles that comprise the majority of ambient particulate matter mass.

3.2.5 Construction Emissions (Short-Term Impacts)

General Construction Information

During construction, short-term degradation of air quality may occur due to the release of particulate emissions (airborne dust) generated by excavation, grading, hauling, and various other construction-related activities. Exhaust emissions from construction equipment also are expected and would include CO, NO_X, VOCs, directly-emitted PM (PM_{10} and $PM_{2.5}$), and toxic air contaminants such as diesel PM. Ozone is not directly emitted from construction activities; it is a regional pollutant that is formed from NO_X and VOCs in the presence of sunlight and heat.

Construction of the proposed project is planned to commence in 2018 and is anticipated to be completed in 2020. The duration of construction for the Build Alternatives is approximately 30 months (2.5 years). Construction will occur in four phases due to the scale of the proposed project and the need to minimize traffic impacts and maintain traffic during construction. These four phases include Grubbing/Land Clearing, Grading/Excavation, Drainage/Utilities, and Paving.

The temporary impact analysis described below utilizes the SMAQMD's Roadway Construction Emissions Model (RoadMod) Version 8.1.0, published June 2016 to quantify emissions associated with roadway construction. RoadMod is a data-entry spreadsheet that utilizes various sources to estimate construction emissions, including OFFROAD and EMFAC2014. Construction of the Build Alternatives involves the same general level of activity. Therefore, one model run was used to evaluate construction emissions for all Build Alternatives. The project-specific assumptions used for the construction calculations are summarized as follows:

- A 2018 start date
- A 30-month construction period
- A 0.6-mile corridor length
- A 2.4-acre project area
- A maximum of acres of land disturbed per day
- A maximum of 2.4 acres of land disturbed per day
- Soil import would include a maximum of 1,500 cubic yards per day
- Soil export would include a maximum of 1,000 cubic yards per day
- Water trucks used as control measure for fugitive dust

The above assumptions were used as input parameters to the RoadMod model. RoadMod is specifically developed to estimate emissions associated with roadway construction projects since the default equipment, activities, and typical phasing are different than those of land use development projects and building construction projects. The methodologies and assumptions used in RoadMod are appropriate for road construction projects, including new road construction, road widening and bridge or overpass construction. The RoadMod phasing

assumptions were used to allocate the project specific construction equipment to the specific phases. Calculation methods and assumptions as generated by RoadMod are provided in the Appendix C.

Table 3-8 shows the estimated daily emissions associated with each construction phase. The emissions were estimated using RoadMod Version 8.1.0 and the assumptions listed in the **Appendix A**. When construction information was not available, the analysis relies on RoadMod default assumptions. The construction schedule indicates that maximum emissions would be generated during overlap of Grubbing/Excavation, Drainage/Utilities/Subgrade, Movable Span, and Approach Span. In the project area, the regulation of air quality on the east side of the Sacramento River is under the jurisdiction of the SMAQMD. The regulation of air quality on the west side of the Sacramento River is under the jurisdiction of the YSAQMD. Based on information provided by the project engineers, it was assumed that 50 percent of daily emissions would be generated within each jurisdiction. Daily emissions would vary and typically be less than the maximum emissions presented in the table.

/a/ total emissions for each air district is calculated assuming a 50/50 split of total project emissions between the SMAQMD and YSAQMD.
tpy - tons per year
ppd - pounds per day
SOURCE: Emission rates from the CARB EMFAC and OFFROAD models.

Some phases of construction, particularly asphalt paving, may result in short-term odors in the immediate area of each paving site(s). Such odors would quickly disperse to below detectable levels as distance from the site(s) increases.

Because Caltrans has Statewide jurisdiction and the setting for projects varies so extensively across the State, Caltrans has not and will not develop thresholds of significance for CEQA. Further, because most air district thresholds have not been established by regulation or by delegation from a federal or State agency with regulatory authority over Caltrans, Caltrans is not required to adopt those thresholds in Caltrans' documents. Nevertheless, SMAQMD and YSAQMD thresholds of significance are provided for reference.

Avoidance, Minimization, and Mitigation Measures

To control the generation of construction-related PM_{10} emissions, the project proponent will follow Standard Specification Section 14, "Environmental Stewardship," which addresses the contractor's responsibility on many items of concern, such as: air pollution; protection of lakes, streams, reservoirs, and other water bodies; use of pesticides; safety; sanitation; convenience for the public; and damage or injury to any person or property as a result of any construction operation. Section 14-9.02, which includes specifications relating to air pollution control by complying with air pollution control rules, regulations, ordinances, and statutes that apply to work performed under the contract, including air pollution control rules, regulations, ordinances, and statutes provided in Government Code Section 11017 (Public Contract Code Section 10231). Section 14-9.03 is directed at controlling dust. In addition, Caltrans Standard Specifications for construction (Sections 10 and 18 for dust control and Section 39-3.06 for asphalt concrete plants) will be adhered to in order to reduce emissions generated by construction equipment.

The best available control measures shall be incorporated into the project commitments. With implementation of standard construction measures (providing 50 percent effectiveness) such as frequent watering (e.g., minimum twice per day), fugitive dust and exhaust emissions from construction activities would not result in any adverse air quality impacts with implementation of the project.

Implementation of the following measures would help to reduce construction impacts:

AQ-1 The contractor shall obtain all necessary Sacramento County and Yolo County permits and approvals and shall follow all required County laws and procedures and respect to best management practices, grading and excavation for the proposed project and all construction-related and emission-generating activities.

AQ-2 Construction of the project shall comply with SMAQMD and YSAQMD Basic Construction Emission Control Practices, Exhaust Control Practices, and Fugitive PM Dust Control Practices.

AQ-3 Construction activity within The Railyards Specific Plan area shall comply with the mitigation measures contained in the adopted Mitigation Monitoring and Reporting Plan for The Railyards development (City of Sacramento 2007). Wet suppression and wind speed reduction are the two most common methods used to control open dust sources at construction sites because a source of water and material for wind barriers tend to be readily available on a construction site.

3.2.6 Naturally Occurring Asbestos and Structural Asbestos

Naturally occurring asbestos (NOA) can be released from serpentinite and ultramafic rocks when the rock is broken or crushed. According to the USGS Survey Map for Asbestos in California, there is no occurrence of asbestos reported within a 25-mile vicinity of the project area. Although it is not anticipated that construction activity would encounter NOA, the project

dust control measures would effectively control unanticipated NOA exposure through a variety of required control measures including watering.

Regarding structural asbestos, National Emission Standards for Hazardous Air Pollutants (NESHAP) regulations require an owner or operator of a demolition or renovation project to thoroughly inspect the affected facility or part of the facility where the demolition or renovation operation will occur for the presence of asbestos prior to the commencement of that project. Four viaduct structures being removed as part of the project date to the 1930s and 1950s and have elements that could contain asbestos.[16] Per NESHAP regulations and SMAQMD Rule 902 (Asbestos), the proposed project would be required to develop an Asbestos Compliance Plan. Refer to the hazards analysis in the Draft Environmental Document for a complete discussion on asbestos hazards and related avoidance, minimization, and/or mitigation measures.

3.2.7 Lead

Aerially deposited lead has been found to occur in soils adjacent to highways and high use roadways. The lead is presumably from the historical use of leaded gasoline and subsequent exhaust emissions. There is potential for encountering aerially deposited lead during construction and grading activities within the proposed project limits in West Sacramento along C Street, 2nd Street and at the bridge approach/viaduct leading from C Street.[17] A majority of the area adjacent to C Street is covered sidewalk; therefore, an aerially deposited lead assessment would be limited to areas with exposed soils in that area.

There is potential for encountering aerially deposited lead during construction and grading activities within the proposed project limits in Sacramento at the bridge approach/viaduct leading from I Street. In addition, the bridge landing within the Sacramento City limits is located within an area under evaluation as part of the Sacramento Railyards remediation and is not likely to exhibit concentrations of elevated aerially deposited lead; however, Jibboom Street and Bercut Drive, in various alignments, have been present since 1916 and therefore have the potential to be impacted with aerially deposited lead. Testing indicate that soils from the assessment area would be classified as either non-hazardous or as soil acceptable for management.

The I Street Bridge and its associated approaches are proposed for demolition or modification. Testing identified three locations with paint containing more than 5,000 parts per million lead: silver paint on metal bridge structure, black paint on metal bridge structure, and white paint on metal northeast approach. In addition, the gasket located at the base of the light boxes on the northeast approaches was determined to be pure lead.

The proposed project would be required to develop a Lead Compliance Plan. Refer to the hazards analysis in the Draft Environmental Document for a complete discussion on lead hazards and related avoidance, minimization, and/or mitigation measures.

3.2.8 Climate Change Analysis

Climate change analyses presented in the following sections estimate and analyze the GHG emissions associated with construction and operations of the proposed project.

[16]Blackburn Consulting, *Draft Initial Site Assessment for the I Street Bridge Replacement Project*, July 2015.

[17]*Ibid*.

Operational Emissions

Similar to the regional air quality analysis above, GHG emissions were estimated using emission factors from the CARB EMFAC2014 model. GHG emissions are presented in **Tables 3-9** for 2020 and **3-10** for 2040. Emissions were estimated using CARB's EMFAC2014 model. Currently, there are no Federal or State standards set for CO_2 emissions. The estimated emissions are only useful for a comparison between alternatives. The numbers are not necessarily an accurate reflection of what the true CO_2 emissions would be because CO_2 emissions are dependent on other factors that are not part of the model, such as the fuel mix, rate of acceleration, and the aerodynamics and efficiency of the vehicles. Refer to Appendix D for a summary of limitations and uncertainties associated with the emissions modeling.

TABLE 3-9: ESTIMATED 2020 ANNUAL GHG EMISSIONS

Source	Metric Tons per Year

Net Change from Existing Conditions	(946,145) (6%)

SOURCE: Emission rates from the CARB EMFAC2014 model.

Construction Emissions

Construction GHG emissions include emissions produced as a result of material processing, emissions produced by onsite construction equipment, and emissions arising from traffic delays due to construction. Construction GHG emissions are presented in **Table 3-11**. The CEQA baseline emissions for construction are zero. Construction emissions were estimated using RoadMod, which is based on the EMFAC and OFFROAD models. The emissions factors for calculating N_2O and CH_4 emissions were obtained from the 2015 Climate Registry Default Emission Factors Construction and Mining Equipment. Construction of the proposed project would occur for 30 months and a total of 2,470 metric tons of carbon dioxide would be generated, equal to an average of 988 metric tons of carbon dioxide per year.

TABLE 3-11: ESTIMATED GHG EMISSIONS FOR CONSTRUCTION ACTIVITY

Alternative	Carbon Dioxide Equivalent	
	Metric Tons per Year	Total Metric Tons
Bridge Construction	988	2,470

SOURCE: Roadway Construction Emissions Model and project-specific construction information.

GHG emissions will be produced at different levels throughout the construction phase; their frequency and occurrence can be reduced through innovations in plans and specifications and by implementing better traffic management during construction phases. In addition, with innovations such as longer pavement lives, improved traffic management plans, and changes in materials, the GHG emissions produced during construction can be mitigated to some degree by longer intervals between maintenance and rehabilitation events.

Appendix B

Incomplete or Unavailable Information

for Project Specific

Mobile Air Toxic Health Impact Analysis

Incomplete or Unavailable Information for Project-Specific Mobile Source Air Toxic Health Impact Analysis

In FHWA's view, information is incomplete or unavailable to credibly predict the project-specific health impacts due to changes in MSAT emissions associated with a proposed set of highway alternatives. The outcome of such an assessment, adverse or not, would be influenced more by the uncertainty introduced into the process through assumption and speculation rather than any genuine insight into the actual health impacts directly attributable to MSAT exposure associated with a proposed action.

The U.S. EPA is responsible for protecting the public health and welfare from any known or anticipated effect of an air pollutant. They are the lead authority for administering the FCAA and its amendments and have specific statutory obligations with respect to hazardous air pollutants and MSATs. The U.S. EPA is in the continual process of assessing human health effects, exposures, and risks posed by air pollutants. They maintain IRIS, which is "a compilation of electronic reports on specific substances found in the environment and their potential to cause human health effects." Each report contains assessments of noncancerous and cancerous effects for individual compounds and quantitative estimates of risk levels from lifetime oral and inhalation exposures with uncertainty spanning perhaps an order of magnitude.

Other organizations are also active in the research and analyses of the human health effects of MSATs, including the HEI. Two HEI studies are summarized in Appendix D of FHWA's Interim Guidance Update on Mobile Source Air Toxic Analysis in NEPA Documents. Among the adverse health effects linked to MSAT compounds at high exposures are cancer in humans in occupational settings; cancer in animals; and irritation to the respiratory tract, including the exacerbation of asthma. Less obvious is the adverse human health effects of MSAT compounds at current environmental concentrations or in the future as vehicle emissions substantially decrease.

The methodologies for forecasting health impacts include emissions modeling, dispersion modeling, exposure modeling, and then final determination of health impacts, with each step in the process building on the model predictions obtained in the previous step. All are encumbered by technical shortcomings or uncertain science that prevents a more complete differentiation of the MSAT health impacts among a set of project alternatives. These difficulties are magnified for lifetime (i.e., 70 year) assessments, particularly because unsupportable assumptions would have to be made regarding changes in travel patterns and vehicle technology, which affects emissions rates, over that time frame because such information is unavailable.

It is particularly difficult to reliably forecast 70-year lifetime MSAT concentrations and exposure near roadways; to determine the portion of time that people are actually exposed at a specific location; and to establish the extent attributable to a proposed action, especially given that some of the information needed is unavailable.

There are considerable uncertainties associated with the existing estimates of toxicity of the various MSATs because of factors such as low-dose extrapolation and translation of occupational exposure data to the general population, which is a concern expressed by HEI. As a result, there is no national consensus on air dose-response values assumed to protect the public health and welfare for MSAT compounds and, in particular, for diesel particulate matter. The U.S. EPA and HEI have not established a basis for quantitative risk assessment of diesel PM in ambient settings.

There is also a lack of national consensus on an acceptable level of risk. The current context is the process used by U.S. EPA as provided by the FCAA to determine whether more stringent controls are required to provide an ample margin of safety to protect public health or to prevent an adverse environmental effect

for industrial sources subject to the maximum achievable control technology standards, such as benzene emissions from refineries. The decision framework is a two-step process. The first step requires the U.S. EPA to determine a "safe" or "acceptable" level of risk due to emissions from a source, which is generally no greater than approximately 100 in a million. Additional factors are considered in the second step, the goal of which is to maximize the number of people with risks less than 1 in a million due to emissions from a source. The results of this statutory two-step process do not guarantee that cancer risks from exposure to air toxics are less than 1 in a million; and in some cases, the residual risk determination could result in maximum individual cancer risks that are as high as approximately 100 in a million. In a June 2008 decision, the U.S. Court of Appeals for the District of Columbia Circuit upheld U.S. EPA's approach to addressing risk in its two-step decision framework. Information is incomplete or unavailable to establish that even the largest of highway projects would result in levels of risk greater than safe or acceptable.

Because of the limitations in the methodologies for forecasting health impacts described, any predicted difference in health impacts between alternatives is likely to be much smaller than the uncertainties associated with predicting the impacts. Consequently, the results of such assessments would not be useful to decision makers, who would need to weigh this information against project benefits, such as reducing traffic congestion, accident rates, and fatalities, plus improved access for emergency response, that are better suited for quantitative analysis.

Appendix C

Road Construction Emission Model (RoadMod)

Assumptions and Results

The maximum pounds per day in row 11 is summed over overlapping phases, but the maximum tons per phase in row 34 is not summed over overlapping phases.

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns G and H. Total PM2.5 emissions shown in Column I are the sum of exhaust and fugitive dust emissions shown in columns J and K.

CO2e emissions are estimated by multiplying mass emissions for each GHG by its global warming potential (GWP), 1 , 25 and 298 for CO2, CH4 and N2O, respectively. Total CO2e is then estimated by summing CO2e estimates over all GHGs.

Road Construction Emissions Model
Data Entry Worksheet

Version 8.1.0

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells D10 through D24, E28 through G35, and D38 through D41 for all project types.
Please use "Clear Data Input & User Overrides" button first before changing the Project Type or begin a new project.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Input Type

Project Name	I-Street Bridge Construction - Phases 1 to 4	
Construction Start Year	2018	Enter a Year between 2014 and 2025 (inclusive)
Project Type	3	1) New Road Construction : Project to build a roadway from bare ground, which generally requires more site preparation than widening an existing roadway 2) Road Widening : Project to add a new lane to an existing roadway 3) Bridge/Overpass Construction : Project to build an elevated roadway, which generally requires some different equipment than a new roadway, such as a crane 4) Other Linear Project Type: Non-roadway project such as a pipeline, transmission line, or levee construction
Project Construction Time	10.25	months
Working Days per Month	22.00	days (assume 22 if unknown)
Predominant Soil/Site Type: Enter 1, 2, or 3 (for project within "Sacramento County", follow soil type selection instructions in cells E18 to E20 otherwise see instructions provided in cells J18 to J22)	1	1) Sand Gravel : Use for quaternary deposits (Delta/West County) 2) Weathered Rock-Earth : Use for Laguna formation (Jackson Highway area) or the Ione formation (Scott Road, Rancho Murieta) 3) Blasted Rock : Use for Salt Springs Slate or Copper Hill Volcanics (Folsom South of Highway 50, Rancho Murieta)
Project Length	0.61	miles
Total Project Area	2.43	acres
Maximum Area Disturbed/Day	2.43	acres
Water Trucks Used?	1	1. Yes 2. No

Please note that the soil type instructions provided in cells E18 to E20 are specific to Sacramento County. Maps available from the California Geologic Survey (see weblink below) can be used to determine soil type outside Sacramento County.

http://www.conservation.ca.gov/cgs/information/geologic_mapping/Pages/googlemaps.aspx#regionalseries

Material Hauling Quantity Input

Material Type	Phase	Haul Truck Capacity (yd^3) (assume 20 if unknown)	Import Volume (yd^3/day)	Export Volume (yd^3/day)
Soil	Grubbing/Land Clearing		0.00	0.00
	Grading/Excavation	12.00	1500.00	1000.00
	Drainage/Utilities/Sub-Grade		0.00	0.00
	Paving		0.00	0.00
Asphalt	Grubbing/Land Clearing		0.00	0.00
	Grading/Excavation		0.00	0.00
	Drainage/Utilities/Sub-Grade		0.00	0.00
	Paving		0.00	0.00

Mitigation Options

On-road Fleet Emissions Mitigation		Select "2010 and Newer On-road Vehicles Fleet" option when the on-road heavy-duty truck fleet for the project will be limited to vehicles of model year 2010 or newer
Off-road Equipment Emissions Mitigation		Select "20% NOx and 45% Exhaust PM reduction" option if the project will be required to use a lower emitting off-road construction fleet. The SMAQMD Construction Mitigation Calculator can be used to confirm compliance with this mitigation measure (http://www.airquality.org/ceqa/mitigation.shtml). Select "Tier 4 Equipment" option if some or all off-road equipment used for the project meets CARB Tier 4 Standard

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells D50 through D53, and F50 through F53.

Construction Periods	User Override of Construction Months	Program Calculated Months	User Override of Phase Starting Date	Program Default Phase Starting Date
Grubbing/Land Clearing	0.25	1.03	5/1/2018	1/1/2018

Road Construction Emissions Model
Data Entry Worksheet

Version 8.1.0

Note: Required data input sections have a yellow background.
Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.
The user is required to enter information in cells D10 through D24, E28 through G35, and D38 through D41 for all project types.
Please use "Clear Data Input & User Overrides" button first before changing the Project Type or begin a new project.

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

SACRAMENTO METROPOLITAN AIR QUALITY MANAGEMENT DISTRICT

Input Type

Project Name	I-Street Bridge Construction - Phases 5 to 7	
Construction Start Year	2018	Enter a Year between 2014 and 2025 (inclusive)
Project Type	3	1) New Road Construction : Project to build a roadway from bare ground, which generally requires more site preparation than widening an existing roadway 2) Road Widening : Project to add a new lane to an existing roadway 3) Bridge/Overpass Construction : Project to build an elevated roadway, which generally requires some different equipment than a new roadway, such as a crane 4) Other Linear Project Type: Non-roadway project such as a pipeline, transmission line, or levee construction
Project Construction Time	19.75	months
Working Days per Month	22.00	days (assume 22 if unknown)
Predominant Soil/Site Type: Enter 1, 2, or 3 (for project within "Sacramento County", follow soil type selection instructions in cells E18 to E20 otherwise see instructions provided in cells J18 to J22)	1	1) Sand Gravel : Use for quaternary deposits (Delta/West County) 2) Weathered Rock-Earth : Use for Laguna formation (Jackson Highway area) or the Ione formation (Scott Road, Rancho Murieta) 3) Blasted Rock : Use for Salt Springs Slate or Copper Hill Volcanics (Folsom South of Highway 50, Rancho Murieta)
Project Length	0.61	miles
Total Project Area	2.43	acres
Maximum Area Disturbed/Day	2.43	acres
Water Trucks Used?	1	1. Yes 2. No

Please note that the soil type instructions provided in cells E18 to E20 are specific to Sacramento County. Maps available from the California Geologic Survey (see weblink below) can be used to determine soil type outside Sacramento County.

http://www.conservation.ca.gov/cgs/information/geologic_mapping/Pages/googlemaps.aspx#regionalseries

Material Hauling Quantity Input

Material Type	Phase	Haul Truck Capacity (yd^3) (assume 20 if unknown)	Import Volume (yd^3/day)	Export Volume (yd^3/day)
Soil	Grubbing/Land Clearing	0.00	0.00	0.00
	Grading/Excavation	0.00	0.00	0.00
	Drainage/Utilities/Sub-Grade	0.00	0.00	0.00
	Paving	0.00	0.00	0.00
Asphalt	Grubbing/Land Clearing	0.00	0.00	0.00
	Grading/Excavation	0.00	0.00	0.00
	Drainage/Utilities/Sub-Grade	0.00	0.00	0.00
	Paving	0.00	0.00	0.00

Mitigation Options

On-road Fleet Emissions Mitigation		Select "2010 and Newer On-road Vehicles Fleet" option when the on-road heavy-duty truck fleet for the project will be limited to vehicles of model year 2010 or newer
Off-road Equipment Emissions Mitigation		Select "20% NOx and 45% Exhaust PM reduction" option if the project will be required to use a lower emitting off-road construction fleet. The SMAQMD Construction Mitigation Calculator can be used to confirm compliance with this mitigation measure (http://www.airquality.org/ceqa/mitigation.shtml). Select "Tier 4 Equipment" option if some or all off-road equipment used for the project meets CARB Tier 4 Standard

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells D50 through D53, and F50 through F53.

Construction Periods	User Override of Construction Months	Program Calculated Months	User Override of Phase Starting Date	Program Default Phase Starting Date
Grubbing/Land Clearing	18.00	1.98	7/1/2018	1/1/2018
Grading/Excavation	7.00	7.90	5/1/2018	7/3/2019
Drainage/Utilities/Sub-Grade	5.00	6.91	4/1/2020	2/1/2020
Paving	0.00	2.96		7/3/2020
Totals (Months)	30		Note: You have entered a non-default starting date. Please provide starting date for all phases, or default values for other phases will be used.	

Please note: You have entered a different number of months than the project length shown in cell D16.
Note: Soil Hauling emission default values can be overridden in cells D61 through D64, and F61 through F64.

Soil Hauling Emissions User Input	User Override of Miles/Round Trip	Program Estimate of Miles/Round Trip	User Override of Truck Round Trips/Day	Default Values Round Trips/Day	Calculated Daily VMT
Miles/round trip: Grubbing/Land Clearing	0.00	30.00		0	0.00

Appendix D

Summary of Limitations and Uncertainties Associated With Emissions Modeling

Limitations and Uncertainties with Modeling

EMFAC

Although EMFAC can calculate CO_2 emissions from mobile sources, the model does have limitations when it comes to accurately reflecting changes in CO_2 emissions due to impacts on traffic. According to the National Cooperative Highway Research Program report, *Development of a Comprehensive Modal Emission Model* (April 2008) and a 2009 University of California study (Barth and Boriboonsomsin 2009), brief but rapid accelerations, such as those occurring during congestion, can contribute significantly to a vehicle's CO_2 emissions during a typical urban trip. Current emission-factor models are insensitive to the distribution of such modal events (i.e., cruise, acceleration, deceleration, and idling) in the operation of a vehicle and instead estimate emissions by average trip speed. This limitation creates an uncertainty in the model's results when compared to the estimated emissions of the various alternatives with baseline in an attempt to determine impacts. Although work by EPA and the ARB is underway on modal-emission models, neither agency has yet approved a modal emissions model that can be used to conduct this more accurate modeling.

The ARB is currently not using EMFAC to create its inventory of greenhouse gas emissions. It is unclear why the ARB has made this decision. Their website only states:

> REVISION: Both the EMFAC and OFFROAD Models develop CO2 and CH4 [methane] emission estimates; however, they are not currently used as the basis for [ARB's] official [greenhouse gas] inventory which is based on fuel usage information. . . However, ARB is working towards reconciling the emission estimates from the fuel usage approach and the models. (California Air Resources Board 2010)

Other Variables

With the current science, project-level analysis of greenhouse gas emissions has limitations. Although a greenhouse gas analysis is included for this project, there are numerous key greenhouse gas variables that are likely to change dramatically during the design life of the proposed project and would thus dramatically change the projected CO_2 emissions.

First, vehicle fuel economy is increasing. The EPA's annual report, "Light-Duty Automotive Technology and Fuel Economy Trends: 1975 through 2012 ," which provides data on the fuel economy and technology characteristics of new light-duty vehicles including cars, minivans, sport utility vehicles, and pickup trucks, confirms that average fuel economy has improved each year beginning in 2005, and is now at a record high (U.S. Environmental Protection Agency 2013). Corporate Average Fuel Economy (CAFE) standards remained the same between model years 1995 and 2003 and subsequently began setting increasingly higher fuel economy standards for future vehicle model years. The EPA estimates that light duty fuel economy rose by 16% from 2007 to 2012. Table E-1 shows the increases in required fuel economy standards for cars and trucks between Model Years 2012 and 2025 as available from the National Highway Traffic Safety Administration for the 2012-2016 and 2017-2025 CAFE Standards.

Table E-1. Average Required Fuel Economy (mpg)

	2012	2013	2014	2015	2016	2018	2020	2025
Passenger Cars	33.3	34.2	34.9	36.2	37.8	41.1 to 41.6	44.2 to 44.8	55.3 to 56.2
Light Trucks	25.4	26	26.6	27.5	28.8	29.6 to 30.0	30.6 to 31.2	39.3 to 40.3
Combined	29.7	30.5	31.3	32.6	34.1	36.1 to 36.5	38.3 to 38.9	48.7 to 49.7
Source: U.S. Environmental Protection Agency 2013								

Second, near zero carbon vehicles will come into the market during the design life of this project. According to the 2013 Annual Energy Outlook:

> "LDVs that use diesel, other alternative fuels, hybrid-electric, or all-electric systems play a significant role in meeting more stringent GHG emissions and CAFE standards over the projection period. Sales of such vehicles increase from 20 percent of all new LDV sales in 2011 to 49 percent in 2040 in the AEO2013 Reference case." (U.S. Energy Information Administration 2013)

The greater percentage of alternative fuel vehicles on the road in the future will reduce overall GHG emissions as compared to scenarios in which vehicle technologies and fuel efficiencies do not change.

Third, California has recently adopted a low-carbon transportation fuel standard in 2009 to reduce the carbon intensity of transportation fuels by 10 percent by 2020. The regulation became effective on January 12, 2010 (codified in title 17, California Code of Regulations, Sections 95480-95490). Beginning January 1, 2011, transportation fuel producers and importers must meet specified average carbon intensity requirements for fuel in each calendar year.

Lastly, driver behavior has been changing as the U.S. economy and oil prices have changed. In its January 2008 report, "Effects of Gasoline Prices on Driving Behavior and Vehicle Market," the Congressional Budget Office found the following results based on data collected from California (U.S. Congressional Budget Office 2008):

1. freeway motorists adjust to higher gas prices by making fewer trips and driving more slowly;
2. the market share of sports utility vehicles is declining; and
3. the average prices for larger, less-fuel-efficient models declined from 2003 to 2008 as average prices for the most-fuel-efficient automobiles have risen, showing an increase in demand for the more fuel efficient vehicles.

More recent reports from the Energy Information Agency and Bureau of Economic Analysis also show slowing re-growth of vehicle sales in the years since its dramatic drop in 2009 due to the Great Recession as gasoline prices continue to climb to $4 per gallon and beyond (U.S. Energy Information Administration 2013: Table 53, U.S. Bureau of Economic Analysis 2014).

Limitations and Uncertainties with Impact Assessment

Taken from p. 5-22 of the National Highway Traffic Safety Administration Final EIS for MY2017-2025 CAFE Standards (July 2012), Figure illustrates how the range of uncertainties in assessing greenhouse gas impacts grows with each step of the analysis:

> "Moss and Schneider (2000) characterize the "cascade of uncertainty" in climate change simulations Figure). As indicated in Figure , the emission estimates used in this EIS have narrower bands of uncertainty than the global climate effects, which are less uncertain than regional climate change effects. The effects on climate are, in turn, less uncertain than the impacts of climate change on affected resources (such as terrestrial and coastal ecosystems, human health, and other resources […] Although the uncertainty bands broaden with each successive step in the analytic chain, all values within the bands are not equally likely; the mid-range values have the highest likelihood."(National Highway Traffic Safety Administration 2012:5-21).

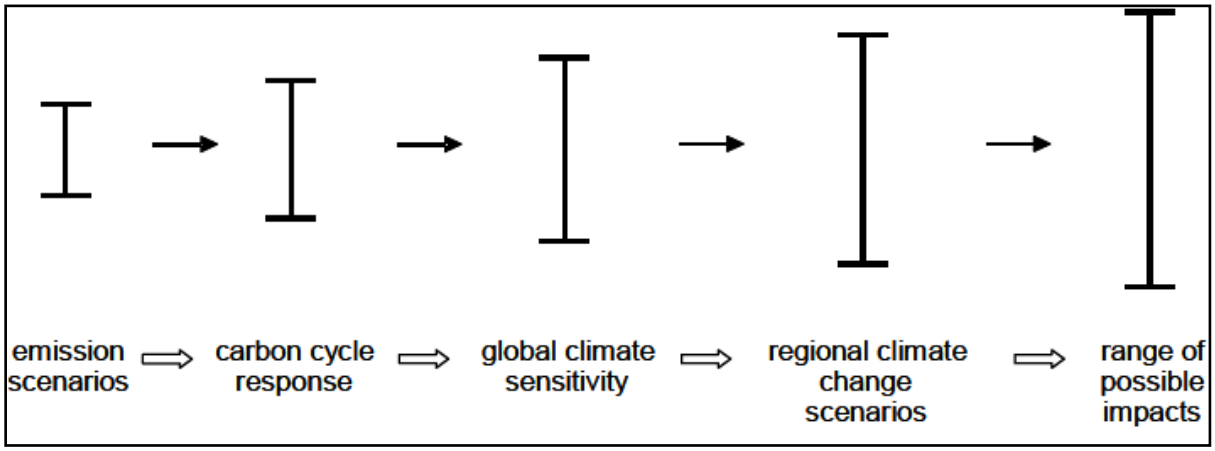

Figure E-1. Cascade of Uncertainties

Much of the uncertainty in assessing an individual project's impact on climate change surrounds the global nature of the climate change. Even assuming that the target of meeting the 1990 levels of emissions is met, there is no regulatory or other framework in place that would allow for a ready assessment of what any modeled increase in CO_2 emissions would mean for climate change given the overall California greenhouse gas emissions inventory of approximately 430 million tons of CO_2 equivalent. This uncertainty only increases when viewed globally. The IPCC has created multiple scenarios to project potential future global greenhouse gas emissions as well as to evaluate potential changes in global temperature, other climate changes, and their effect on human and natural systems. These scenarios vary in terms of the type of economic development, the amount of overall growth, and the steps taken to reduce greenhouse gas emissions. Non-mitigation IPCC scenarios project an increase in global greenhouse gas emissions by 9.7 up to 36.7 billion metric tons CO_2 from 2000 to 2030, which represents an increase of between 25 and 90%. (Intergovernmental Panel on Climate Change 2007)

The assessment is further complicated by the fact that changes in greenhouse gas emissions can be difficult to attribute to a particular project because the projects often cause shifts in the locale for some type of greenhouse gas emissions, rather than causing "new" greenhouse gas emissions. It is difficult to assess the extent to which any project level increase in CO_2 emissions represents

a net global increase, reduction, or no change; there are no models approved by regulatory agencies that operate at the global or even statewide scale.

Top 4 Summary: Highest 4 Daily Maximum State 24-Hour Sulfur Dioxide Averages

at Sacramento-Del Paso Manor

	2010		2011		2012	
	Date	24-Hr Average	Date	24-Hr Average	Date	24-Hr Average
First High:	Jan 29	0.001	Sep 6	0.001	Aug 14	0.002
Second High:	Jan 27	0.001	Aug 26	0.001	Jul 4	0.001
Third High:	Jan 25	0.001	Sep 7	0.001	Jul 2	0.001
Fourth High:	Jan 23	0.001	Sep 10	0.001	Jan 9	0.001
Annual Average:		0.000		0.000		*
Year Coverage:		96		83		67

Notes:

Hourly sulfur dioxide measurements and related statistics are available at Sacramento-Del Paso Manor between 1980 and 2012. Some years in this range may not be represented.

All averages expressed in parts per million.

An exceedance of a standard is not necessarily related to a violation of the standard.

Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

* means there was insufficient data available to determine the value.

Available Pollutants:

8-Hour Ozone | Hourly Ozone | PM2.5 | PM10 | Carbon Monoxide | Nitrogen Dioxide | State Sulfur Dioxide | Hydrogen Sulfide

California Environmental Protection Agency
Air Resources Board

Year Coverage:		94		93		98

Notes:

Daily PM2.5 averages and related statistics are available at Sacramento-T Street between 1998 and 2014. Some years in this range may not be represented.
All averages expressed in micrograms per cubic meter.
An exceedance of a standard is not necessarily related to a violation of the standard.
State statistics are based on California approved samplers, whereas national statistics are based on samplers using federal reference or equivalent methods. State and national statistics may therefore be based on different samplers.
Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

3-Year Maximum Annual Average:		20		19		19
Year Coverage:		98		100		24

Notes:

Daily PM10 averages and related statistics are available at Sacramento-T Street between 1990 and 2014. Some years in this range may not be represented.

All averages expressed in micrograms per cubic meter.

The national annual average PM10 standard was revoked in December 2006 and is no longer in effect. Statistics related to the revoked standard are shown in *italics* or *italics* .

An exceedance of a standard is not necessarily related to a violation of the standard.

All values listed above represent midnight-to-midnight 24-hour averages and may be related to an exceptional event.

State and national statistics may differ for the following reasons:

- State statistics are based on California approved samplers, whereas national statistics are based on samplers using federal reference or equivalent methods. State and national statistics may therefore be based on different samplers.
- State statistics for 1998 and later are based on local conditions (except for sites in the South Coast Air Basin, where State statistics for 2002 and later are based on local conditions). National statistics are based on standard conditions.
- State criteria for ensuring that data are sufficiently complete for calculating valid annual averages are more stringent than the national criteria.

Measurements are usually collected every six days. Measured days counts the days that a measurement was greater than the level of the standard; Estimated days mathematically estimates how many days concentrations would have been greater than the level of the standard had each day been monitored.

3-Year statistics represent the listed year and the 2 years before the listed year.

Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

* means there was insufficient data available to determine the value.

Chapter 1 Proposed Project

1.1 Purpose of a Community Impact Assessment

The purpose of a community impact assessment (CIA) is to consider how a project would affect the people, businesses, neighborhoods, communities, and social and economic characteristics of an area. This CIA serves as one of the background technical reports that will be used to prepare relevant sections of the environmental document for the proposed project.

A CIA is "a process to evaluate the effects of a transportation action on a community and its quality of life" (Federal Highway Administration 1996). It describes the relevant existing conditions within an area; potential impacts of the project on the community and its neighborhoods; and potential measures to best avoid, minimize, or compensate for any adverse community impacts of a proposed project.

This document has been prepared to provide the California Department of Transportation (Caltrans), the Cities of Sacramento and West Sacramento, and the public with information about the socioeconomic and community-level effects of construction and operation of the I Street bridge Replacement Project (project).

This report identifies impacts associated with land use changes, social effects, property acquisitions, and economic changes; it also addresses environmental justice issues. The report was prepared according to the *Community Impact Assessment, Caltrans Standard Environmental Reference, Environmental Handbook 4* (California Department of Transportation 2011), which contains Caltrans guidelines for preparing socioeconomic assessments and Federal Highway Administration (FHWA) guidelines.

1.2 Introduction

The City of Sacramento, in cooperation with the City of West Sacramento and Caltrans, proposes to construct a new bridge over the Sacramento River to replace the vehicle crossing that is currently accommodated by the existing I Street Bridge in order to remove a series of functionally obsolete or structurally deficient bridges (i.e., approach structures). The new connection also would reduce future traffic congestion, improve operations and safety, serve multiple modes of transportation, and comply with current American Association of State Highway and Transportation Officials (AASHTO), Caltrans, and local agency design standards.

The project is subject to state and federal environmental review requirements because of use of federal Highway Bridge Program (HBP) funds from the FHWA. Accordingly, project documentation is being prepared in compliance with both the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA). The City of Sacramento is the lead agency under CEQA, with the City of West Sacramento as a responsible agency, and Caltrans is the lead agency under NEPA. The FHWA's other responsibilities for environmental review, consultation, and any other action required in accordance with applicable federal laws

for this project will be carried out by Caltrans under its assumption of responsibility pursuant to 23 United States Code (USC) 327.

This project is included in the Sacramento Area Council of Governments (SACOG) 2035 *Metropolitan Transportation Plan/Sustainable Communities Strategy* (MTP/SCS).

1.2.1 Project Location

The proposed project is located over the Sacramento River between the cities of Sacramento and West Sacramento, approximately 1,000 feet north of the existing I Street Bridge (Figure 1-1). The project limits starting within the City of Sacramento consist of Railyards Boulevard from 200 feet east of Bercut Drive on the east, continuing west over the Sacramento River into the City of West Sacramento along C Street, and terminating approximately 100 feet west of the 5th Street intersection. The project limits also extend along Bercut Drive approximately 500 feet north of Railyards Boulevard, along Jibboom Street 550 feet north of Railyards Boulevard and 300 feet south of Railyards Boulevard, along 3rd Street 50 feet north and south of C Street, along 4th Street 50 feet north and south of C Street, and along 5th Street 50 feet north and south of C Street. The total length of the project is approximately 0.42 mile along C Street and Railyards Boulevard.

1.3 Purpose and Need

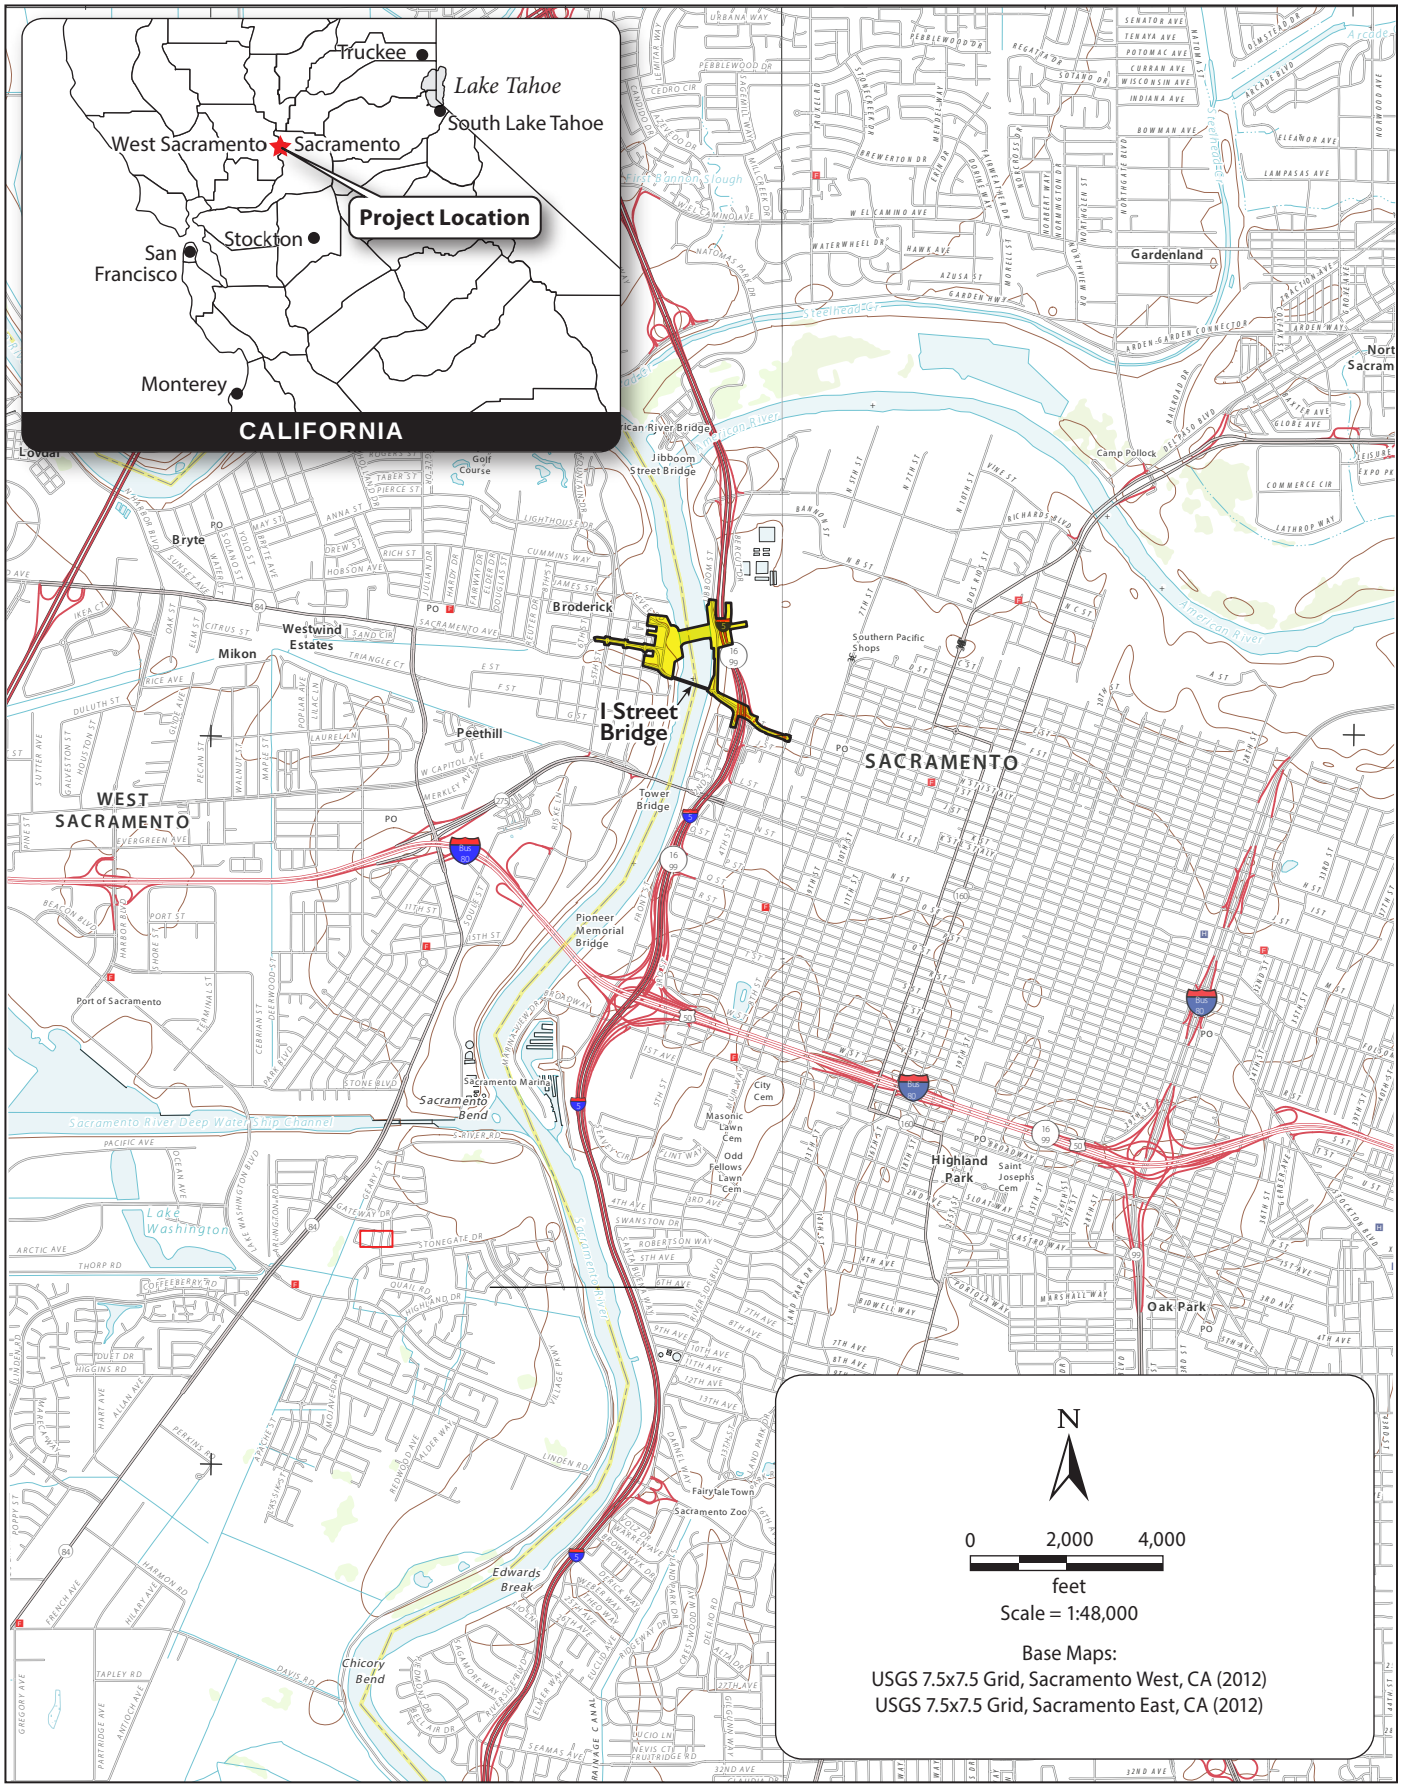
The proposed project would construct a new bridge over the Sacramento River between the Cities of Sacramento and West Sacramento to replace the vehicle crossing that is currently provided by the existing I Street Bridge. Construction of the proposed project has independent utility; the project is not dependent on other projects or improvements to meet the purpose and need.

Termini for the proposed project were developed through an iterative process involving engineering design and traffic operations analysis. Preliminary design concepts were tested with the traffic operations analysis model to evaluate how lane configurations influenced peak-hour conditions.

1.3.1 Purpose

The purpose and objectives of the project are listed below.

- The project should construct a new public crossing of the Sacramento River north of the Union Pacific Railroad-owned I Street Bridge from C Street in the City of West Sacramento to Railyards Boulevard in the City of Sacramento, consistent with the adopted findings of the Sacramento River Crossings Alternatives Study for Bridge Location 2 in the North Market Area.



Graphics ... 00203.14 (6/19/15) AB

Figure 1-1
Vicinity Map

- The new bridge should meet the requirements of the Neighborhood Friendly Bridge definition that the City of Sacramento City Council adopted by resolution on October 18, 2011, which is defined by the following elements.
  - A facility whose primary function is local connectivity rather than regional travel and primarily serves short local trips.
  - A bridge which serves all users, including motorists, bicyclists, pedestrians, low energy vehicles, and public transit riders.
  - A bridge with aesthetics and dimensions which are architecturally pleasing and contextually appropriate for the adjacent neighborhoods.
  - A bridge that does not exceed or expand the already-planned capacity of the approach roadways (i.e., no widening of approaches just to accommodate bridge flows).
  - A facility which is designed with a target speed equal to or less than the approach roadways.
  - A bridge which reduces the growth in vehicle miles traveled in the adjacent communities.
  - A bridge that does not connect directly to streets which are primarily residential in character.
  - A bridge that is consistent with the Need and Purpose statement [the adopted Sacramento River Crossings Alternatives Study statement] as articulated.
- In addition to the Neighborhood Friendly Bridge definition, the project should include pedestrian and bicycle facilities in the new public crossing that meet Americans with Disabilities Act (ADA) requirements, and facilitate connections to and from the new crossing and the Sacramento River Parkway and Riverfront Park trails.
- The proposed project also would need to construct a movable bridge that satisfies the vertical clearance and river navigation requirements of the U.S. Coast Guard (USCG).
- The project design should not preclude future addition of a streetcar, a separate, stand-alone project being developed by the Cities of West Sacramento and Sacramento.
- The new bridge also is intended to improve the connectivity to, and accessibility of, businesses, recreational areas, and new or redevelopment opportunity sites located in the urban core of Sacramento and West Sacramento.

1.3.2 Need

The project is needed for the following reasons.

- The existing I Street Bridge does not fully comply with current design and traffic operation standards due to the following conditions.
  - I Street Bridge limits or restricts traffic capacity and multimodal use. The current bridge width is not sufficient to provide adequate traffic operations, bicycle lanes, or the ability for transit service across the bridge.

  - The I Street Bridge and the four associated approach structures are on the federal eligible bridge list for federal funds for replacement and/or rehabilitation through the HBP. The I Street Bridge has been classified as functionally obsolete, and the existing approach structures have been classified as structurally deficient. The Cities of Sacramento and West Sacramento have decided to pursue replacement through the HBP.

- As adopted by the Sacramento City Council, new crossings of the Sacramento River between the City of Sacramento and City of West Sacramento shall be Neighborhood Friendly. In coordination with staff from the City of West Sacramento and SACOG, the definition for a Neighborhood Friendly Bridge was developed by the City of Sacramento and the Sacramento City Council adopted the definition by resolution in October 2011. The replacement bridge structure is required to be consistent with the Neighborhood Friendly Bridge definition.
- In addition to the Neighborhood Friendly Bridge requirements, lack of ADA compliance, non-standard and non-continuous sidewalks, and lack of bicycle facilities discourage walking and bicycling on the existing I Street Bridge.
- Section 9 of the Rivers and Harbors Act requires any local, state, or federal agency planning to construct a bridge over a navigable waterway to apply for a bridge permit through the USCG. The USCG requires the new bridge to meet or exceed the existing vertical clearance along the river, which is currently set by the US 50 Pioneer Bridge. In order to comply with the Neighborhood Friendly Bridge definition and meet the USCG requirements for navigation clearance, the new bridge will need to be movable.
- The SACOG MTP/SCS identifies that a proposed streetcar will cross over the new bridge from Sacramento to West Sacramento. While the streetcar will be a separate, stand-alone project, the bridge design must not preclude the future addition of a streetcar.
- Limited connectivity to the riverfront reduces the potential to achieve planned urban development and redevelopment of opportunity sites identified in the adopted plans of Sacramento and West Sacramento.

1.4 Project Description

This section describes the proposed action and the design alternatives that were developed to meet the identified need through accomplishing the defined purpose(s), while avoiding or minimizing environmental impacts. The alternatives under consideration are one bridge alignment for the new bridge over the Sacramento River and two alternatives for portions of the roadway design in Sacramento and in West Sacramento.

- City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection
  - Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive
  - Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

- City of West Sacramento Residential Access
  - Alternative 1—C Street Connection to B Street
  - Alternative 2—C Street Connection to 3rd Street
- No-Build (No-Project) Alternative

The proposed project is located in Sacramento and Yolo Counties, over the Sacramento River and between the Cities of Sacramento and West Sacramento, and approximately 1,000 feet north of the existing I Street Bridge (Figure 1-1). The total length of the project is approximately 0.42 mile along C Street and Railyards Boulevard. The purpose of the project is to construct a new public crossing of the Sacramento River north of the Union Pacific Railroad-owned I Street Bridge from C Street in the City of West Sacramento to Railyards Boulevard in the City of Sacramento in order to remove a series of functionally obsolete or structurally deficient bridges, consistent with the adopted findings of the Sacramento River Crossings Alternatives Study for Bridge Location 2 in the North Market Area.

1.4.1 Build Alternatives

One alignment is proposed for the new bridge over the Sacramento River. A new approximately 860-foot bridge, consisting of two vehicle lanes, on-street Class II bike lanes, and sidewalks along both sides, is proposed. The bridge would include two fixed-span approach structures, approximately 200 feet and 270 feet in length, that tie into the Sacramento and West Sacramento banks of the river, respectively. The center span of the bridge would be an approximately 330-foot movable span that meets the USCG requirements. Roadway improvements on Railyards Boulevard in Sacramento and C Street in West Sacramento also are proposed. In both Sacramento and West Sacramento, two alternatives for portions of the roadway design are being considered.

- City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection
  - Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive
  - Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

In the City of Sacramento, Alternative 1 consists of a signalized intersection at Jibboom Street and Bercut Drive, while Alternative 2 consists of a roundabout between these two intersections. Beyond the Jibboom Street and Bercut Drive intersections, the remaining project elements and limits in the City of Sacramento are similar under both alternatives.

- City of West Sacramento Residential Access
  - Alternative 1—C Street Connection to B Street
  - Alternative 2—C Street Connection to 3rd Street

In the City of West Sacramento, the proposed C Street alignment would cut off access to four residential parcels and one multifamily parcel located along 2nd Street, north of C Street. Two alternatives are proposed for maintaining access to these parcels. Alternative 1 would construct a

new connection to C Street, approximately 150 feet east of the C Street/3rd Street intersection, that would extend north to B Street and then ultimately connect to the 3rd Street/B Street intersection. Alternative 2 would connect to the same location at C Street as Alternative 1, approximately 150 feet east of the C Street/3rd Street intersection, but would continue north approximately 300 feet, then make a 90-degree left turn, and connect to 3rd Street approximately 300 feet north of C Street.

1.4.1.1 Common Design Features of the Build Alternatives

The proposed project would construct a new bridge over the Sacramento River between Sacramento and West Sacramento to replace the vehicular crossing that is provided by the existing I Street bridge. The project would facilitate vehicular and multimodal traffic over the river in order to reduce traffic congestion, improve safety, and remove a number of structurally deficient or functionally obsolete bridges that have reached the limit of their design life. While the existing I Street Bridge over the Sacramento River would remain in-place, the approach structures leading up to the bridge from both directions would be demolished. See Figure 1-2 for a depiction of the project limits and the approach structures that would be removed.

The Sacramento River is considered to be a navigable waterway of the United States. Under the provisions of the General Bridge Act of 1946, as amended, the USCG must approve proposed location and plans for bridges over navigable waters of the United States prior to commencing construction. In order to comply with the adopted Neighborhood Friendly Bridge definition and the USCG requirement to maintain navigation along the river, the new bridge is proposed to be a movable bridge.

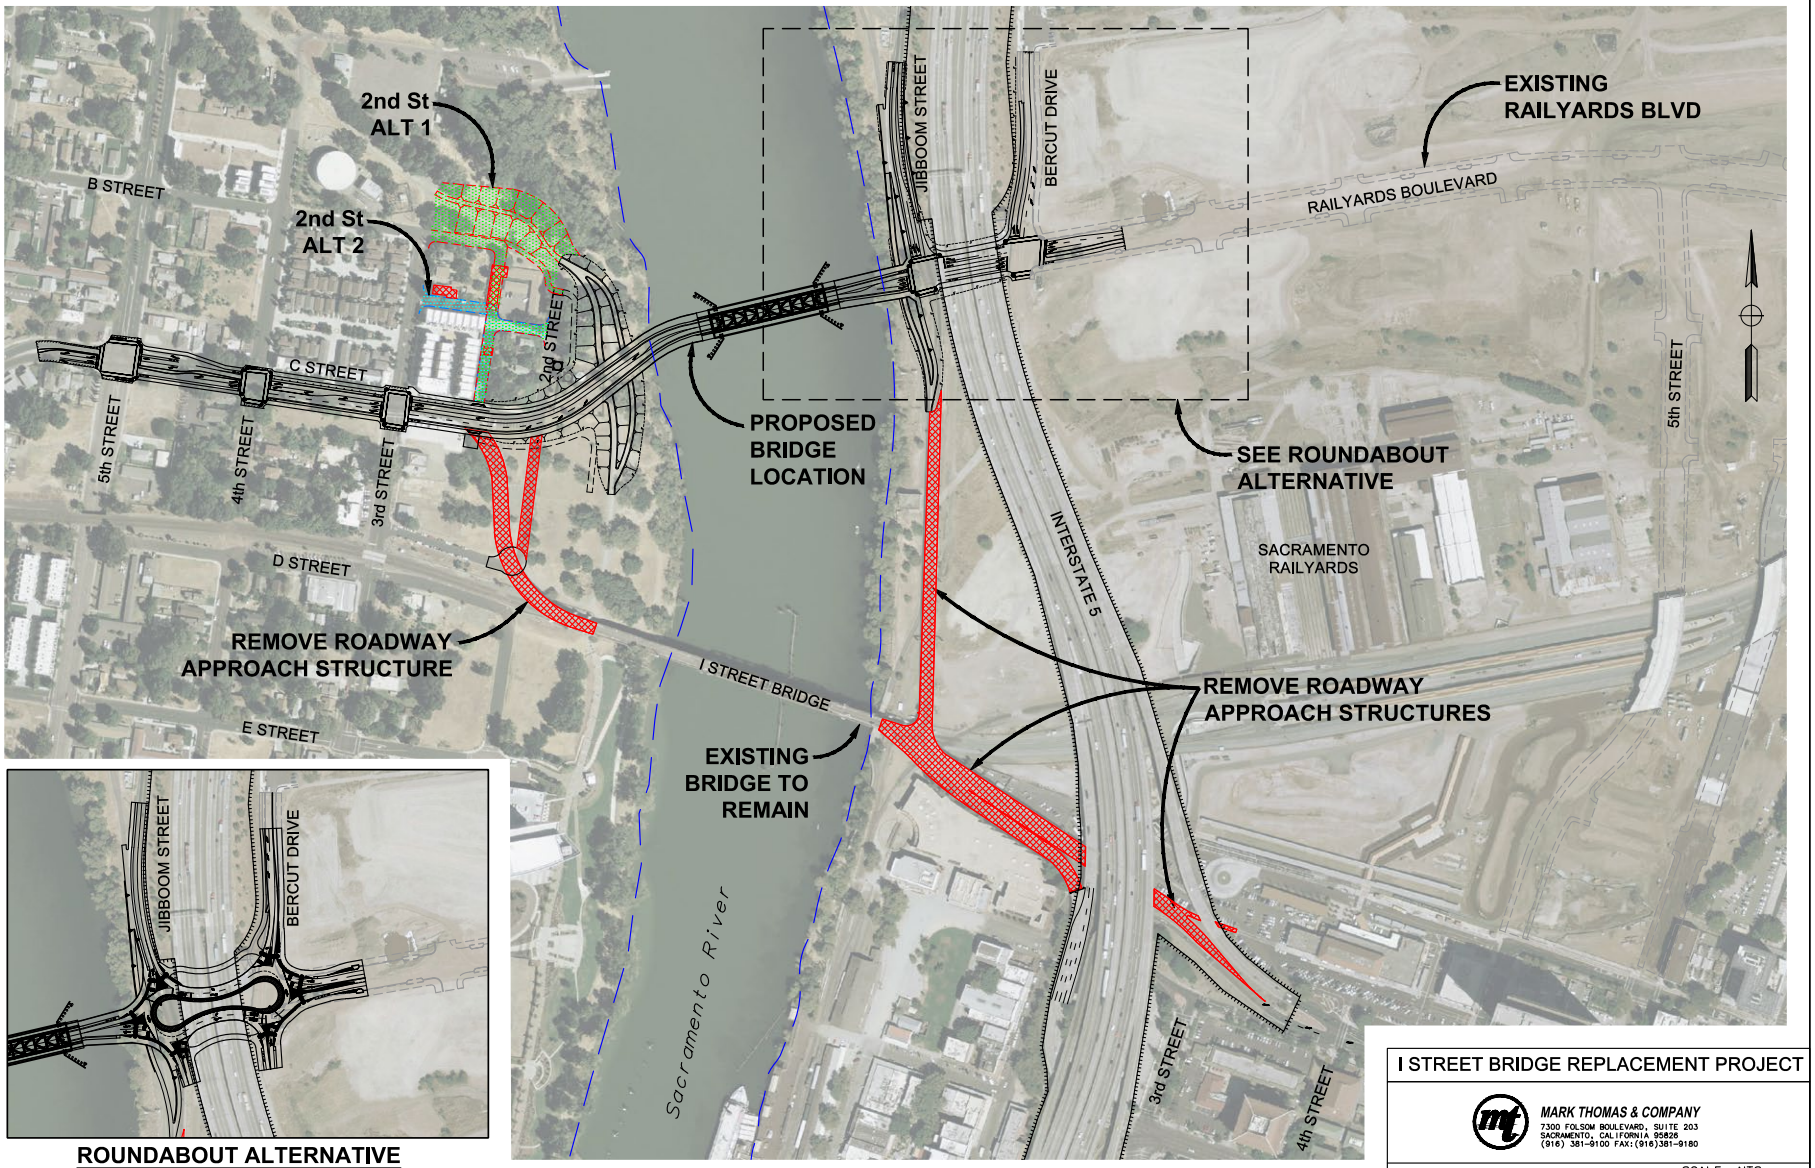
Common design features of the build alternatives are listed below.

New Bridge Construction and Roadway Modifications

Bridge Construction

The proposed project would construct a new bridge over the Sacramento River. The total bridge length would be approximately 860 feet long, consisting of two vehicle lanes, on-street Class II bike lanes, and sidewalks along both sides of the bridge. The bridge would include two fixed-span approach structures that tie into the Sacramento and West Sacramento banks of the river and are approximately 200 feet and 270 feet in length, respectively. The center span of the bridge would be a movable span that meets the USCG requirements. The movable span is anticipated to be approximately 330 feet in length. The bridge soffit elevation would be set 3 feet above the 200-year water surface elevation to comply with the Central Valley Flood Protection Board (CVFPB) freeboard requirements.

The two fixed-span approach structures would be 72 feet wide, with a superstructure depth (or total bridge thickness) of approximately 6 feet. Each approach structure would be a two-span bridge. The abutment at one end of the structure would be constructed on the banks of the river, a center pier would be placed within the river approximately around the existing bank toe of slope, and the other end of the approach structure would be constructed on the piers for the movable span.



Graphics ... 00203.14 (6/19/15) AB

Figure 1-2
Proposed Project

Based on coordination with the USCG, the movable span would provide a 278-foot clear channel opening approximately centered at the middle of the river. As such, the movable span has been identified as a vertical lift bridge, which would raise the bridge to a minimum vertical clearance of 59 feet over the maximum river elevation of 31 feet (measured to the NGVD 29 vertical datum). The truss depth of the movable span would be approximately 40 feet, with 6 feet of the structure being below the bridge deck and 34 feet above the bridge deck. The vertical towers would be approximately 130 feet tall, measured from the bridge soffit elevation. The vertical towers would be approximately 33 feet in thickness and the same width as the bridge deck. The total bridge width on the movable span would be 81 feet.

Due to the existing soil conditions, the bridge would be constructed on deep pile foundations. The abutments for the fixed-span approach structures at the river bank would consist of approximately 50 piles per abutment that are driven or cast-in-drill-hole (CIDH), to a depth of approximately 70 feet below the original ground elevation. The center piers for the two fixed-span approach structures (located approximately at the bank toe of slope in the river, below the ordinary high water mark) would consist of 50 driven or CIDH piles per pier that are approximately 70 feet below the original ground elevation. If driven piles are selected for either the abutments or piers, the piles would be precast concrete or steel. The foundations for the movable span would consist of four large-diameter cast-in-steel-shell piles per pier. Each pile would be 9 feet in diameter, extending approximately 140 feet below the original ground elevation.

Erosion control measures would be installed around the proposed bridge foundations to prevent future scour at the bridge supports. It is anticipated that rock slope protection (RSP) would be installed around the bridge abutments and piers within the water to control erosion.

A bridge fender system also is planned around the movable span piers to protect the piers from errant watercrafts that are navigating along the river. The fender system would include approximately 30 driven concrete or wooden piles around each of the movable span piers. The piles would be driven to a depth of approximately 30 feet below the original ground elevation.

Temporary Falsework

Temporary falsework platforms would be required to construct the proposed bridge foundations and approach structures. The platforms would be constructed using temporary piles within the river that would be installed on or after April 15; they would be removed by October 31 of each year, and following completion of construction. In addition, temporary cofferdams would be required to construct the bridge piers within the water. The cofferdams would consist of temporary sheetpiles installed around the individual piers. Dewatering inside the cofferdams would be required.

Roadway Modifications

City of Sacramento

In Sacramento, Bercut Drive would be modified from Railyards Boulevard north approximately 500 feet. Bercut Drive would be designed to have two northbound lanes at the Railyards

Boulevard intersection, tapering down to one northbound lane at the northern project limits, and one southbound lane. Improvements to Bercut Drive south of Railyards Boulevard are not part of, nor needed for, the proposed project and would be constructed if needed as part of a separate future project.

Proposed improvements on Jibboom Street would extend 550 feet north of Railyards Boulevard. The roadway would consist of one travel lane in each direction, on-street Class II bike lanes, sidewalk along the west side of the roadway, and retaining walls of various heights along both sides of the road. Extension of Jibboom Street south of Railyards Boulevard is not included with, nor needed for, the proposed project and would be constructed if needed as part of a separate future project.

The proposed roadway profile for Railyards Boulevard would be approximately 6 feet higher than the original ground elevation at the Jibboom Street intersection. The profile adjustment is needed in order to satisfy the CVFPB requirements to provide 3 feet of clearance between the 200-year-flood water surface elevation and the bridge soffit (or low chord of the bridge).

City of West Sacramento

Between the bridge touchdown location along C Street in West Sacramento and the 4th Street/ C Street intersection, the roadway would consist of one westbound travel lane, two eastbound travel lanes (the two eastbound travel lanes would taper down to one eastbound lane east of the 3rd Street intersection), a center left-turn lane, on-street Class II bike lanes, on-street parking along the north side of the roadway, and sidewalks along both sides of the roadway. As the roadway through this section currently consists of the proposed number of travel lanes, the widening through this area is primarily needed to support the Class II bike lanes and wider sidewalks.

Along C Street between 4th Street and 5th Street, the roadway would consist of one travel lane in each direction, left-turn lanes, on-street Class II bike lanes, and sidewalks along both sides of the road. All of the improvements through this section would be accommodated within the existing roadway limits.

Class I Bikeway and Levee Modifications and Improvements

City of Sacramento

The existing Class I Sacramento River Parkway along Jibboom Street would be reconstructed approximately 500 feet north and 300 feet south of Railyards Boulevard as part of the proposed project. In order to maintain a continuous off-street Class I path along this section, the path would be grade-separated under the proposed bridge structure. Cyclists and pedestrians approaching Railyards Boulevard in either direction would have the option to continue along the path under the new structure, avoiding the need to cross the roadway. Cyclists and pedestrians who are traveling along the path also would have the option to connect to Railyards Boulevard and cross over the proposed bridge into West Sacramento or turn east into Sacramento. Due to the limited horizontal clearance between the river and the Interstate-5 (I-5) viaduct structure, retaining walls would be needed along the path to account for the vertical elevation difference

between Jibboom Street and the path that continues under the proposed bridge structure. The maximum retaining wall height along the bike path would be 16 feet.

City of West Sacramento

The proposed project would require improvements to the existing levee along the West Sacramento side of the river, where the proposed bridge alignment would connect to C Street. The existing levee does not meet current standards required by Title 23 of the California Code of Regulations. Extending approximately 300 feet north and south of the proposed C Street alignment, the levee cross-section would be reconstructed to meet current design standards, which would require 3:1 side slopes on the landside and waterside of the levee, and a 20-foot-wide crown at the top of the levee. The levee improvements also would include a slurry cutoff wall extending to a depth of 110 feet below the original ground elevation. In addition, the proposed roadway profile would be approximately 6 feet higher than the original ground elevation as it crosses over the levee. In order to maintain access to the levee for inspection and maintenance services, access roads would be constructed from the new roadway to the top of the improved levee section. The proposed grading for the levee would require relocation of the existing water tower that is located along 2nd Street, just north of the proposed C Street alignment. The tower would be relocated to the northwest, approximately 43 feet from its existing location.

The new levee maintenance road also would serve as the future Class I River Walk Park trail extension in West Sacramento. Similar to the trail improvements proposed as part of the project in Sacramento, the trail would be grade-separated under the proposed bridge structure. Cyclists and pedestrians approaching C Street in either direction would have the option to continue along the trail under the new structure, avoiding the need to cross the roadway. Cyclists and pedestrians who are traveling along the trail also would have the option to connect to C Street to cross over the proposed bridge into Sacramento or head west on C Street.

Storm Water Drainage Management

Drainage for the proposed roadway would be conveyed to the existing storm drain system installed within Railyards Boulevard and C Street. Railyards Boulevard currently drains storm water to the east along the roadway and then into a retention basin south of Railyards Boulevard. C Street drains storm water west along the roadway and then ultimately south beyond the project limits.

As is standard with all construction projects, the contractor would be required to install temporary best management practices (BMPs) to control any runoff or erosion from the project site into the surrounding waterways. These temporary BMPs would be installed prior to any construction operations and would be in place for the duration of the contract. The removal of these BMPs would be the final operation, along with project site cleanup.

Structure Demolition and Roadway Modifications

Following completion of the new bridge connections at Railyards Boulevard and C Street, traffic would be diverted to the new bridge, and the four existing approach structures to the I Street

Bridge would be removed. Bridge numbers 24C0364L, 24C0364R, 22-0033, and 22C0154 would be demolished and the foundations would be removed to a depth of 3 feet below the original ground elevation. Encroachment permits from Caltrans and Union Pacific Railroad would be needed to complete the bridge removal. The existing I Street Bridge is owned and operated by Union Pacific Railroad and would continue to remain in-place and used by trains following construction of the new bridge.

As part of the removal of the existing approach structures, the project would include modifications to I Street within the City of Sacramento from the southbound I-5 on-ramp east to the 5th Street intersection. The modification would include signing and striping revisions, demolition of existing roadway sections that are no longer required, and removal of bridge abutments and foundations.

Staging, Storage, and Proposed Access during Construction

Two staging areas would be used to store materials and equipment during construction, such as pipe materials, precast manholes and drop inlets, steel girders, piles, and rebar, along with the construction equipment when not in use. One area would be located south of Railyards Boulevard under I-5 in Sacramento; the other area would be located west of the landward side of the levee, south of the new bridge location in West Sacramento. The staging area located along Railyards Boulevard would be accessed via the existing intersection at Jibboom Street. The staging area in West Sacramento would be accessed via the existing 2nd Street connection at 3rd Street, south of C Street. The staging areas would be in use throughout the construction duration; the areas would be returned to their pre-project conditions at the completion of the project.

Utility Relocations

A number of public and private utilities would need to be relocated or adjusted to grade as part of the project, including existing water, sewer, gas, electric, and communication facilities within Jibboom Street, Bercut Drive, C Street, and 2nd Street.

Traffic Management and Detours during Construction

While most of the project would be constructed outside of existing roadways, some areas would require temporary detours or staged construction.

Along Jibboom Street at the proposed Railyards Boulevard intersection, the new roadway profile would be raised approximately 6 feet above the original ground elevation. To maintain access to the existing Jibboom Street viaduct south of Railyards Boulevard during the roadway construction, a temporary access road would be needed. The proposed temporary access road would connect to the existing Jibboom Street viaduct abutment approximately 350 feet south of Railyards Boulevard. The temporary road would then continue under I-5 and connect to the Railyards Boulevard/Bercut Drive intersection. The temporary road would require placement of temporary fill material and a roadway structural section that would be removed after construction of the new bridge. Traffic traveling north along Jibboom Street would continue north along Bercut Drive to access the Richards Boulevard/I-5 interchange.

In order to complete the improvements at Jibboom Street and Railyards Boulevard, Jibboom Street would be closed to traffic approximately 600 feet north of Railyards Boulevard. Traffic traveling south along Jibboom Street to continue over the existing I Street Bridge into West Sacramento would be detoured over to Bercut Drive at Richards Boulevard. Traffic would then use the temporary access road to connect to the Jibboom Street viaduct structure. The temporary access road would be in place for approximately 2 years, after which traffic would use the new roadways and new bridge.

The Sacramento River Parkway trail along Jibboom Street also would require temporary re-routing during construction. The temporary alignment for the trail would follow the temporary Jibboom Street alignment south of Railyards Boulevard. Cyclists and pedestrians would then continue following a detour north along Bercut Drive to Richards Boulevard, where they could then connect back to the Parkway on the west side of I-5. The detour would be in place for approximately 2 years.

During construction, traffic along C Street would be maintained along the existing approach structure until the new bridge is constructed.

Project Construction Sequence

New bridge and roadway construction would occur first, followed by demolition of the four approach structures that connect to the existing I Street Bridge. Once the new bridge and roadways are constructed, traffic would be diverted to the new bridge in order to allow demolition adjacent to the existing bridge. Construction of the project is expected to take approximately 30 months.

Property Acquisition

The project would require temporary and permanent property acquisitions along C Street, 3rd Street, and 2nd Street within the City of West Sacramento and along Railyards Boulevard, Jibboom Street, Bercut Drive, and I Street within the City of Sacramento.

Along C Street, temporary and permanent acquisitions would be required along the south side of the roadway to accommodate the construction of standard shoulders, bike lanes, and sidewalks—from the intersection of 4th Street to the Sacramento River.

Along 3rd Street and 2nd Street, temporary and permanent acquisitions would be needed from the Union Pacific Railroad on the south, to just north of the B Street intersections, for construction of the proposed roadway and levee improvements.

Along Railyards Boulevard, Jibboom Street, and Bercut Drive, temporary and permanent acquisition would be needed from the current state-owned right-of-way for I-5, for construction of the roadway. In addition, temporary and permanent acquisitions would be needed along Jibboom Street for the proposed temporary detour road and Class I bikeway improvements.

Temporary acquisition would be required along the existing I Street connection to facilitate removal of the existing viaduct structures. Due to the limited space available in Old Sacramento,

it is anticipated that construction activities would occur from the parking lot at the intermodal station.

1.4.1.2 Unique Features of Build Alternatives

In both the City of Sacramento and the City of West Sacramento, two alternatives for portions of the roadway design are being considered.

City of Sacramento Railyards Boulevard/Jibboom Street/Bercut Drive Intersection

Alternative 1 consists of a signalized intersection at Jibboom Street and Bercut Drive, while Alternative 2 consists of a roundabout between these two intersections. Beyond the Jibboom Street and Bercut Drive intersections, the remaining project elements and limits are similar under both alternatives.

Alternative 1—Signalized Intersection at Jibboom Street and Bercut Drive

Under Alternative 1, Railyards Boulevard would be extended west over the Sacramento River; east of Bercut Drive. Railyards Boulevard would consist of two westbound lanes and one eastbound lane. Between Jibboom Street and Bercut Drive, Railyards Boulevard would consist of two westbound lanes and three eastbound lanes; two eastbound lanes would be trapped into left-turn lanes onto Bercut Drive, and one eastbound lane would continue along Railyards Boulevard. West of the Jibboom Street intersection, Railyards Boulevard would consist of one lane in each direction.

Alternative 2—Roundabout Intersection at Jibboom Street and Bercut Drive

Under Alternative 2, Railyards Boulevard would be extended west over the Sacramento River. East of Bercut Drive, Railyards Boulevard would consist of two westbound lanes and one eastbound lane. Between Jibboom Street and Bercut Drive, Railyards Boulevard would consist of a roundabout with two lanes in each direction. One westbound lane would be a trap onto northbound Jibboom Street, and one westbound lane would continue onto the new bridge. One eastbound lane would be trapped into left-turn lanes onto Bercut Drive, and one eastbound lane would continue along Railyards Boulevard. West of Jibboom Street, Railyards Boulevard would consist of one lane in each direction.

City of West Sacramento Residential Access

The new C Street alignment would cut off access to four residential parcels and one multifamily parcel located along 2nd Street, north of C Street. Two alternatives are proposed for maintaining access to these parcels.

Alternative 1—C Street Connection to B Street

Alternative 1 would construct a new connection to C Street approximately 150 feet east of the 3rd Street intersection. The new access road would be 30 feet wide, extend north to B Street, and then ultimately connect to the 3rd Street/B Street intersection. This alternative would require

right-of-way acquisitions from six individual parcels and removal of two structures. One structure is located on APN 010-101-010 and appears to be an individual residence. Another structure is located on APN 010-101-013 and appears to be an apartment building that supports up to four individual apartments. As B Street currently is constructed along the existing levee, the roadway improvements also would require an additional 500 feet of improvements to the levee. Similar to the improvements identified along C Street, the levee cross-section would be reconstructed to meet current design standards, which require 3:1 side slopes on the landside and waterside of the levee, with a 20-foot-wide crown at the top of the levee. The levee improvements also would include a slurry cutoff wall that extends to a depth of 110 feet below the original ground elevation.

Alternative 2—C Street Connection to 3rd Street

Alternative 2 would connect to the same location at C Street, approximately 150 feet east of the 3rd Street intersection and continue north approximately 300 feet. This alternative would then make a 90-degree left turn and connect to 3rd Street approximately 300 feet north of C Street. This alternative would require right-of-way acquisition from seven individual parcels and removal of three structures. One structure is located on APN 010-101-010 and appears to be an individual residence. Another structure is located on APN 010-101-013 and appears to be an apartment building that supports up to one individual apartment. The last structure is located on APN 010-101-004 and appears to be an individual residence.

1.4.2 No Build (No-Project) Alternative

Under the No Build Alternative, the existing I Street Bridge would remain in use for vehicle, bicycle, and pedestrian access between the Cities of Sacramento and West Sacramento. No changes to traffic patterns on I Street or C Street would occur. The four approach structures would remain in place and in use; and there would be no changes to existing roadways, levees or Class I bikeways.

Improvements and development of transportation infrastructure would continue following the General Plans of both cities, the Sacramento Railyards Specific Plan (approved December 2007), and the Washington Specific Plan (adopted May 1996). The Sacramento Railyards Specific Plan identifies the extension of Railyards Boulevard west to a Tee intersection at Jibboom Street. Railyards Boulevard at Bercut Drive would consist of two westbound lanes and one eastbound lane. The same number of lanes on Railyards Boulevard would extend west to the intersection with Jibboom Street; at this point, the left westbound lane on Railyards Boulevard would become a dedicated left-turn onto southbound Jibboom Street, and the right westbound lane would be a dedicated right-turn onto northbound Jibboom Street.

In West Sacramento, future changes to C Street would be based on the Washington Specific Plan, which identifies 12-foot-wide sidewalks and 7-foot-wide Class II bike lanes along the roadway. The connection to the I Street Bridge would not change.

Chapter 2 Affected Environment

This chapter discusses the existing economic and demographic character of the study area for the proposed project. As described in Chapter 1, "Introduction," the project area is located over the Sacramento River between the cities of Sacramento and West Sacramento, approximately 1,000 feet north of the existing I Street Bridge (Figures 1-1 and 1-2). For the purposes of this analysis, the study area is considered to be within the U.S. Census Bureau–designated block groups that intersect the project area. Figure 2-1 depicts the CIA study area and shows the individual block groups: CT 101.01 BG 1, CT 101.01 BG 3, CT 101.01 BG 4, CT 07.00 BG 1, and CT 53.01 BG 1.

2.1 Land Use

The project area traverses portions of two counties (Sacramento and Yolo) and two cities (Sacramento and West Sacramento). Overall, the project area is densely developed and is surrounded by commercial, industrial, and residential development.

The portion of the study area east of the Sacramento River and north of the existing I Street Bridge (CT 53.01 BG 1), contains land uses that are primarily industrial and commercial. It is largely made up of the Sacramento Railyards, including the Sacramento Valley/Amtrak station. The Sacramento water treatment plant is located just east of I-5, adjacent to the Railyards, along Bercut Drive. Matsui Waterfront Park, the Sacramento River Parkway and several hotels are located along the Sacramento Riverfront. The American River, Tiscornia Park, and the American River Parkway border this portion of the study area to the north.

The portion of the study area east of the Sacramento River and south of the existing I-Street bridge (CT 07.00 BG 1) is bisected by I-5. Old Sacramento, the City's historic district, is located between the Sacramento River and I-5. The historic district is primarily made up of commercial and recreational uses. The area east of I-5 is made up of commercial uses, including retail, office uses, and government buildings. This area also contains the construction site where a new indoor sports arena is being built.

The portion of the study area west of the Sacramento River and north of the existing I-Street Bridge (CT 101.01 BGs 1 and 3) contains land uses that are primarily recreational and residential. River Walk Park borders the Sacramento River and currently terminates at the I Street Bridge overcrossing. Broderick Boat Ramp and Yolo County Park are also located in this quadrant along the west bank of the river. Residential uses, including single family residences and one multi-family complex along 3rd Street are located behind the recreational/waterfront uses.

The portion of the study area west of the Sacramento River and south of the existing I Street Bridge (CT 101.01 BG 4) contains a variety of land uses. River Walk Park borders the west bank of the Sacramento River and is a prominent recreational feature in this portion of the study area. Two large buildings, the Ziggurat Building and a state building, are located west of River Walk Park. Residential uses are located further west and include single- and multi-family homes.

2.1.1 Land Use Designations

Most of the land in the Sacramento portion of the study area is designated as Urban Center Business District and Urban Center High. Old Sacramento is designated as Traditional Center, and the riverfront is designated as Recreational. See Figure 2-2 for the general plan land use designations in the Sacramento portion of the study area.

The West Sacramento portion of the study area contains a mix of land uses, including single- and multi-family residential, commercial, office, public/quasi public, and industrial. There are several vacant properties in the West Sacramento portion of the study area as well (Mintier Harnish 2009). See Figure 2-3 for the general plan land use designations in the West Sacramento portion of the study area.

2.1.2 Development Trends

2.1.2.1 City of Sacramento

SACOG's 2035 MTP/SCS projects that the region will have approximately 1.3 million employees and 1.2 million housing units by 2035. Sacramento is expected to contain roughly 20 percent of the region's housing and nearly 30 percent of the region's jobs.

The 2035 General Plan identifies that most of the development in the Sacramento portion of the study area will be infill development. In October 2009, the Sacramento City Council identified priority "shovel ready" sites, including Tier One areas where development is likely to occur in the near term. The majority of the Sacramento portion of the study area is identified as a Tier One shovel ready site, with a high likelihood of job and housing growth by 2030 (City of Sacramento 2015).

2.1.2.2 City of West Sacramento

West Sacramento has experienced rapid population growth since 1990, which has brought significant land use change including new residential development in the outlier areas and redevelopment within existing built-up areas. West Sacramento has adopted five specific plans to help guide and implement land use planning in different areas of the city (Mintier Harnish 2009:Figure 2-5). The Washington Specific Plan pertains to land use in the study area.

The Washington Specific plan covers the portion of the study area north of the existing I Street Bridge. It establishes a framework for long-term redevelopment, and includes a single family housing development, the CalSTRS government building, and the Raley's Landing mixed-use project. (City of West Sacramento 1996).

2.1.3 Adopted Plans and Programs

2.1.3.1 City of Sacramento 2035 General Plan

In March of 2015 the City of Sacramento adopted the 2035 General Plan to set a new direction for the future of the city. The 2035 General Plan Vision provides the City's key values and aspirations for Sacramento's future. The overarching Vision of the General plan is to make Sacramento the most livable city in America. In conjunction with the Vision Statement, the City Council adopted Guiding Principles for land use, urban design, housing, mobility, economic development, public safety, environmental resources, parks and recreation, and services and facilities. The principles establish policy benchmarks for the rest of the General Plan. Specific policies and implementation measures of the 2035 General Plan are further discussed in Chapter 3.

2.1.3.2 Railyards Specific Plan

The Railyards Specific Plan (City of Sacramento 2007) comprises a 244-acre area in downtown Sacramento located immediately north of the Central Business District, east of the Sacramento River, south of North B Street and west of the federal courthouse and the Alkali Flat neighborhood. The Sacramento Railyards Specific Plan is intended to advance the policies of the General Plan to create more mixed-use, transit-oriented neighborhoods within the Central City.

2.1.3.3 River District Specific Plan

The City of Sacramento adopted the River District Specific Plan in 2011. This plan establishes planning and design standards for the redevelopment of approximately 773 acres of land located at the confluence of the American and Sacramento Rivers, north of the downtown core of the City of Sacramento. The vision of the River District Specific Plan is to create a vibrant, mixed-use community served by a network of bicycle and pedestrian-friendly routes (City of Sacramento 2011).

2.1.3.4 Sacramento River Parkway Plan

In 1975 the Sacramento River Parkway Master Plan was adopted by the City Council and incorporated into the Open Space Element of the General Plan. It was updated in 1997 to reflect changes in the parkway, including the South Natomas Community Plan area, and other proposed land uses in the downtown area. The Sacramento River Parkway Plan is a twenty year policy guide for habitat restoration and recreational development for lands adjacent to the river (City of Sacramento 1997).

The Sacramento River Parkway Plan area is located along the easterly bank of the Sacramento River within the City limits of Sacramento and is approximately 17 miles in length and 820 acres in area. The boundaries of the area generally are the City limits inclusive of South Natomas to the north, the Sacramento River on the west, City limits at Freeport on the South, and Interstate 5 Freeway on the east (City of Sacramento 1997).

2.1.3.5 The City of Sacramento Pedestrian Master Plan (2006)

The 2006 City of Sacramento Pedestrian Master Plan is a comprehensive vision for improving pedestrian conditions over the next twenty years. The Pedestrian Master Plan presents a set of goals and strategies to achieve this vision and includes a framework for creating an improved pedestrian environment. The overall purpose of the Pedestrian Master Plan is to make Sacramento a model pedestrian-friendly city – the "Walking Capital" (City of Sacramento 2006).

2.1.3.6 2010 Sacramento City/County Bikeway Master Plan

The 2010 City/County Bikeway Master Plan was developed to serve the recreational and transportation needs of the public. The Plan includes all of Sacramento County which consists of 997 square miles and 3,887 miles of public roads. The goal of the Plan is to develop a comprehensive plan which will meet the needs of all bicyclists (Sacramento City-County Bikeway Task Force 2010).

2.1.3.7 Sacramento River Crossings Alternatives Study

In 2010 the City of Sacramento approved a study to analyze the feasibility and impacts of potential new crossings of the Sacramento River. The study evaluates a variety of alternatives including a no-build option to a multiple crossings option. The study resulted in a final report on potential crossings locations, transportation impacts, and cost estimates.

2.1.3.8 City of West Sacramento General Plan

The incorporated City of West Sacramento abuts the City of Sacramento's General Plan Policy Area. West Sacramento's General Plan governs land uses in these areas. The Plan consists of nine sections that describe City policies related to land use, housing, transportation and circulation, public facilities and services, recreational and cultural resources, natural resources, health and safety, urban structure and design, and child care. The Plan also includes a section describing administration and implementation measures. Major land use goals of the Plan include:

- To provide for orderly, well-planned, and balanced growth consistent with the limits imposed by the City's infrastructure and the City's ability to assimilate new growth.
- To designate adequate land in a range of residential densities to meet the housing needs of all income groups expected to reside in West Sacramento.
- To designate adequate land and provide support for the development of commercial uses providing goods and services to West Sacramento residents and West Sacramento's market area.
- To designate adequate land and provide support for the development of office uses serving both West Sacramento and the region.
- To designate adequate land and provide support for light, heavy, and water-related industrial uses that create jobs and enhance the economy of West Sacramento.

- To designate adequate land for development of public and quasi-public uses to support existing and new residential, commercial, and industrial land uses (City of West Sacramento 2000).

Washington Specific Plan

The Washington Specific Plan covers a planning area of approximately 194 acres of urban land near the northeast corner of West Sacramento. The Plan Area is bounded by State Route 275 on the south, the Sacramento River on the east, A Street on the north, and portions of Sixth and Eighth Streets on the west. The Plan is intended to focus efforts by local residents, landowners, developers, and public officials to stimulate a transformation of the Washington area.

The main goals of the Plan are:

- To coordinate efforts between the Cities of West Sacramento and Sacramento.
- To capitalize on the Sacramento River and to make the adjacent areas a regional focal point.
- To integrate economic, residential and social development in the Washington area with the Triangle, Riverfront, and downtown Sacramento areas (City of West Sacramento 1996).

Washington Realized-Sustainable Community Strategy

The Washington Realized, a Sustainable Community Strategy, is intended to shift development patterns toward mixed-use growth that is served by public transit in the Washington Neighbhorhood in West Sacramento. It contains an infill development and infrastructure needs analysis, as well as an analysis of regulatory barriers and tranpsortation management. It also contains a section on neighborhood preservation, as Washington is the oldest neighborhood in West Sacramento. The purpose of Washington Realized is to identify baseline conditions, analyze the strenghths and barriers to sustainable development, and provide strategies and recommendations for action (City of West Sacramento 2015).

2013 West Sacramento Bicycle, Pedestrian, and Trails Master Plan

The main goal of the West Sacramento Bicycle, Pedestrian, and Trails Master Plan (BPTMP) is to create a pedestrian and bicycle-friendly community and to increase the number of people in West Sacramento who bicycle or walk to work, to school, for errands, or for recreation. The BPTMP establishes goals, policies, implementation actions, and priorities for the development of bicycling and walking facilities in West Sacramento, as envisioned by the General Plan (City of West Sacramento 2013).

2.1.4 Parks and Recreational Facilities

Various parks and recreational facilities are scattered throughout the study area (Figure 2-4). The *I Street Bridge 4(f)Report* also discusses parks and recreational facilities in the project area as they relate to Section 4(f) of the Department of Transportation Act of 1966 (ICF International 2015a).

2.1.4.1 City of Sacramento Parks and Recreational Facilities

Tiscornia Park is located in CT 53.01 BG 1 at the confluence of the Sacramento and American Rivers at 195 Jibboom Street. This park provides riverfront access, as well as access to the American River Bike Trail.

Matsui Waterfront Park is located in CT 53.01 BG 1 just south of Tiscornia Park along the Sacramento River. This park connects Old Sacramento to Discovery Park. A second phase of development is planned for this park, which includes a group picnic and BBQ area, parking lot, and rehabilitation of the historic building for community use.

Old Sacramento State Historic Park is located in CT 07.00 BG 1, just south of the existing I Street Bridge and west of I-5. This area contains the Sacramento Railroad Museum and other historic buildings.

Several planned public parks are identified in the Sacramento Railyards Specific Plan. The planned parks and open space areas are shown in Figure 2-4.

2.1.4.2 City of West Sacramento Parks and Recreational Facilities

River Walk Park is located in CT 101.01 BG 4 along the west bank of the Sacramento River between the Tower Bridge and the existing I Street Bridge. This park contains picnic areas and provides access to the Sacramento River Walk Trail.

Broderick Boat Ramp is located in CT 101.01 BG 1, on 4th Street along the west bank of the Sacramento River. It contains a boat dock, covered picnic areas, restrooms, and a fish cleaning station.

There are several proposed parks identified in West Sacramento. River Walk Park will eventually extend from Broderick Boat Ramp to the I-80 river crossing. A 0.75 acre access corridor is proposed just south of the Ziggarat building, between 3rd Street and River Walk Park. Washington Plaza is a 0.38 acre urban plaza that would be located at the corner of 5th Street and E Street and would contain a gathering area, water feature, public art and game tables. Broderick Boat Ramp would be expanded to include a 1.5 acre dog park. Lastly, The City of West Sacramento Parks Master Plan identifies a proposed Governors Residence State Park, which would be located just west of the Sacramento River and north of Broderick Boat Ramp.

2.1.5 Farmland/Timberland

According to the state Farmland Mapping and Monitoring Program, the study area does not contain prime farmland, or farmland of state or local importance. No timberland is present. Farmland and timberland is not discussed further in this document.

2.2 Community Characteristics

This section describes the community characteristics of the study area, including its demographics, presence or lack of cohesion, and community facilities.

2.2.1 Population

There has been considerable growth in the Sacramento area between 2000 and 2010. The City of West Sacramento experienced significant annual growth—5.4%. Regional and local population changes for key jurisdictions from 2000 to 2010 are shown in Table 2-1.

Table 2-1. Existing Regional and Local Population Change

Area	2000	2010	Percent Change (%)	Average Annual Growth Rate (AAGR) (%)
California	33,871,648	36,637,290	8.2	0.8
Sacramento County	1,223,499	1,395,144	14.0	1.6
Yolo County	168,660	200,849	19.1	1.9
City of Sacramento	407,018	466,488	14.6	1.5
City of West Sacramento	31,615	48,744	54.2	5.4

Source: U.S. Census Bureau 2010.

2.2.1.1 Race/Ethnicity

As reported in the 2010 census (U.S. Census Bureau 2010), the total population of the City of Sacramento is 466,488. Of the total population, the largest group is White (approximately 35.5 percent), and persons of Hispanic or Latino origin of any race made up the next largest group (26.9 percent). The remaining population in descending order of proportion is Asian, Black or African American, Two or more races combined, Native Hawaiian/Pacific Islander, American Indian/Alaskan Native, and other (Table 2-2). The total population of the City of West Sacramento is 48,744 (U.S. Census Bureau 2010). Of the total population, the largest group is white (approximately 47.4 percent), and persons of Hispanic or Latino origin of any race made up the next largest group (31.4 percent). The remaining population in descending order of proportion is Asian, Black or African American/Two or more races combined, Native Hawaiian/Pacific Islander, American Indian/Alaskan Native, and other. Table 2-2 indicates the ethnic distribution of the relevant census tracts.

As shown in Table 2-2, several of the block groups within the CIA study area are more ethnically diverse compared to the cities of Sacramento and West Sacramento. CT 07.01 BG 1 and CT 53.01 BG 1 have higher percentages of Black or African American residents, and CT 101.01 BG 3 has a higher percentage of Hispanic residents than average for the cities of Sacramento and West Sacramento.

Table 2-2. Existing Regional and Local Race and Ethnicity Characteristics (2010)*

Area	Total Population	Hispanic or Latino (of Any Race)	%	Not Hispanic or Latino													
				White	%	Black or African American	%	American Indian or Alaskan Native	%	Asian	%	Native Hawaiian/ Pacific Islander	%	Other Race	%	Two or More Races	%

* Refer to Figure 2-1 for location of block groups included in this table

2.2.1.2 Income

According to the 2010 census (U.S. Census Bureau 2010), several block groups in the study area have a notably lower median household income and a lower per capita income than the respective cities, especially CT 07.00 BG 1, CT 53.01 BG 1, and CT 101.01 BG 4. Table 2-3 shows income and poverty statistics in the study area and region.

Table 2-3. Income and Poverty Statistics for the Study Area (2010)*

Area	Median Household Income	Per capita Income
California	$61,094	$29,527
Sacramento County	$55,064	$26,739
Yolo County	$55,918	$27,730
City of Sacramento	$49,753	$25,508
West Sacramento	$53,394	$24,827
CT 07.00 BG 1	$12,403	$10,123
CT 53.01 BG 1	$11,359	$5,453
CT 101.01 BG 1	$67,039	$53,855
CT 101.01 BG 3	$36,162	$16,433
CT 101.01 BG 4	$17,318	$6,783

Source: U.S. Census Bureau 2010.
* Refer to Figure 2-1 for location of census tracts included in this table

2.2.2 Community Cohesion

Community cohesion is the degree to which residents have a sense of belonging to their neighborhood; their level of commitment to the community; or a strong attachment to neighbors, groups, and institutions, usually as a result of continued association over time (Community Impact Assessment Handbook, California Department of Transportation [Caltrans], June 1997).

As described above, the study area is divided from east to west by the Sacramento River. Other dividing factors include I-5 and the UPRR tracks. Pedestrian and bicycle crossing is limited over the river and over/under the freeway and railroad tracks. Crossing these barriers public or private motorized transportation is possible only at designated overpasses.

The Sacramento side of the study area is comprised of a mix of land uses. The portion of the study area east of the Sacramento River and north of the existing I Street Bridge is made up of industrial land use, including the Sacramento Railyards and a WWTP. Old Sacramento is located between the Sacramento River and I-5, and downtown Sacramento is located east of I-5. These areas are mostly comprised of commercial and governmental land uses. There are some residences in this side of the study area, but they are scattered in small clusters. Because the land uses are so varied and because there are few residential uses in this portion of the study area, community cohesion is considered low in the Sacramento portion of the study area.

The West Sacramento side of the portion of the study area includes more residential and recreational uses. This portion of the study area is divided north and south by the UPRR tracks.

The neighborhood north of Sacramento Avenue contains sidewalks, schools, and parks. While there are many new land use changes to the West Sacramento side of the study area, including redevelopment near the waterfront, this neighborhood contains older homes, and residences that have likely been here for longer periods of time. West Sacramento residents shop and recreate locally. These factors indicate a cohesive community.

2.2.3 Community Facilities (Schools, Health Care)

The following section describes the community facilities in the study area. No libraries are located within the study area and libraries are not discussed further in this document. Community facilities and services are shown in Figure 2-4.

2.2.3.1 Schools

As shown in Figure 2-4, few schools are located in the study area. Smythe Academy is located in CT 53.01 BG 1 at 700 Dos Rios in Sacramento, approximately 1.12 miles northeast of the project boundary. Elkhorn Village Elementary School is located in CT 101.01 BG 3, at 750 Cummins Way in West Sacramento. It is approximately 0.5 miles northwest of the project boundary.

2.2.3.2 Health Care Facilities

There are no health care facilities within in the study area. The nearest major health care facilities to the study area include the UC Davis Medical Center at 2315 Stockton Blvd and Sutter General Hospital at 2801 L Street in Sacramento, and the West Sacramento Medical Center at 155 15th Street in West Sacramento. Health care facilities are not discussed further in this document.

2.2.4 Access, Circulation and Parking

2.2.4.1 Access

The primary roads in the project area and vicinity are shown on Figure 1-1. The I Street Bridge is one of three river crossings that connect Sacramento and West Sacramento, along with the Tower Bridge (Capitol Mall/West Capitol Avenue) and the Pioneer Memorial Bridge (US 50/Business-80). I-5 runs through the study area on the Sacramento side of the river. The primary arterials on the Sacramento side of the study area include I Street and J Street, and 2nd and 5th Streets. The primary arterials on the West Sacramento side of the study area include Jefferson Blvd, Tower Bridge Gateway, and 5th Street. Secondary arterials include Sacramento Avenue, C Street, Riverfront Street, and 3rd Street.

2.2.4.2 Circulation

In addition to roadways, the multimodal transportation system in the study area includes public transit, bikeways, pedestrian pathways/sidewalks and rail service.

Transit and Rail Services

The study area is well served by public transportation. Regional Transit operates a light rail in the Sacramento portion of the study area. The light rail provides service on the gold line from the Sacramento Valley Station (located within CT 53.01 BG 1 in the study area) through Downtown Sacramento and east to Rancho Cordova and Folsom. The blue line of the light rail provides service from South Sacramento near Florin Avenue and Meadowview Road to north Sacramento near Watt Avenue. The newer green line of the light rail provides service from Downtown Sacramento to 7th Street and Richards Boulevard, north of the Sacramento Valley Station. This line is projected to expand in the future north towards the community of Natomas. Regional Transit operates buses on 255 routes in the Sacramento area.

Yolo Bus provides transit service in Yolo County, primarily between Davis, Woodland, West Sacramento, and Sacramento. There are 14 regular bus routes, with an additional 6 commuter bus routes and 7 express bus routes that provide extra service during commute hours.

Pedestrian and Bicycle Facilities

A moderate amount of pedestrian and bicycle facilities are available in the study area. In Sacramento, there is an on-street Class II bike lane on Jibboom Street, and Class III bike lanes on 3rd Street and L Street. There is an off-street bike lane along Capitol Mall, and the Sacramento River Parkway trail is a Class I bike trail, located along the east bank of the Sacramento River throughout the study area. In West Sacramento, C Street is a Class III bike route from 3rd Street to 6th Street, Sacramento Avenue a Class II bike lane, and Lighthouse Drive contains Class I and Class II bike lanes (City of West Sacramento 2013:Figure 3).

Parking

Parking is provided throughout the study area both on-street and in public and private lots. The Sacramento portion of the study area contains various paid parking garages, including one on 3rd Street and L Street and two garages in Old Sacramento. Meter parking is available on most of the Downtown Sacramento and Old Sacramento streets in the study area. On-street parking and a small portion of the Ziggurat Building parking lot is available to the public in the West Sacramento portion of the study area. The government buildings and commercial properties/businesses in the West Sacramento portion of the study contain private lots.

2.3 Public Services and Utilities

The following section discusses public services (which includes police and fire protection) and utilities and communications providers in the study area.

2.3.1 Police Protection

2.3.1.1 City of Sacramento Police Department

The City of Sacramento Police Department, headquartered at 5770 Freeport Boulevard in Sacramento, provides law and traffic enforcement for the portion of the study area within the city of Sacramento. There is one station within the study area at 300 Richards Boulevard. The full-service department had approximately 891 officers in 2012 (sworn and civilian) (City of Sacramento Police Department 2012).

2.3.1.2 City of West Sacramento Police Department

The City of West Sacramento Police Department, headquartered at 550 Jefferson Boulevard in West Sacramento, provides law and traffic enforcement for the portion of the study area within the City of West Sacramento. The Department is divided into three offices: Administration, Investigations (which includes the Code Enforcement Division), and Operations. Police officers patrol 23.3 square miles. The Department is staffed with 71 sworn officers, 23 civilian officers, 8 part time officers, 18 parking enforcement officers, and 4 part-time, non-sworn staff. Other positions in the department include part-time police officers, parking enforcement officers, reserve police officers, and volunteers.

2.3.2 Fire Protection

2.3.2.1 Sacramento Fire Department

The City of Sacramento Fire Department provides fire protection and emergency medical services to the portion of the study area within the Sacramento city limits. Its service area is 146.3 square miles, and it serves a population of 516,167. Of the 24 active stations, the station nearest the project corridor is Station 14 at 1341 C Street in Sacramento. In 2012 the Sacramento Fire Department received 74,130 total calls (City of Sacramento Fire Department 2012).

2.3.2.2 Sacramento Metropolitan Fire District

The Sacramento Metropolitan Fire District (Metro Fire) is a combination of 16 smaller fire districts, including the Sacramento County Fire Protection District, that merged to create a California Special District. Metro Fire provides fire, rescue, and emergency medical services to an area of 417 square miles and a population of 640,000. There are approximately 155 on-duty personnel on any given day. In the 2013/2014 fiscal year, Metro Fire responded to 6,206 service calls (Sacramento Metropolitan Fire District 2015).

2.3.2.3 West Sacramento Fire Department

The West Sacramento Fire Department provides fire protection and emergency response services within the city limits and responds to emergencies in outlying areas when other Departments request aid. The West Sacramento Fire Department has 17 personnel on duty at a given time.

There are five stations in West Sacramento. The two nearest stations to the study area are Station 41 at 132 15th Street and Station 44 at 905 Fremont Street in West Sacramento.

2.3.3 Electricity and Natural Gas

The Sacramento Municipal Utilities District (SMUD) generates, transmits, and distributes electricity to a 900-square-mile territory that includes Sacramento, Sacramento County and a small portion of Placer County (Sacramento Municipal Utilities District 2015). SMUD provides electric service in the Sacramento County portion of the study area.

The Pacific Gas and Electric Company (PG&E) provides natural gas and electric service to approximately 16 million people throughout a 70,000-square-mile service area in northern and central California (Pacific Gas and Electric Company 2015). PG&E provides electric service to the City of West Sacramento, and natural gas service to the entire study area.

2.4 Economic Conditions

This section discusses the economic conditions of the study area and the surrounding region, including employment and income data and a description of business activity in the study area.

2.4.1 Regional Economy and Employment

2.4.1.1 City of Sacramento

In recent years, both residential and commercial development has declined due to a weak housing market, high foreclosure rates, and lack of financing. However, there are some positive trends that indicate this downward economic trend is reversing. Unemployment is falling (14.11 in 2011 to 10.8 in 2013). Sacramento also saw a slight increase in commercial development starting in 2012.

The Economic Development Strategy, adopted by the Sacramento City Council in 2007, establishes citywide economic development priorities. This strategic framework identifies key development opportunity areas and provides implementation plans that will help the City achieve its development goals. The 12th Street corridor, located between UPRR and I Street, is identified as a key area in this plan. The Richards Boulevard corridor, located between 12th Street and Jibboom Street, is also identified as a key area. The Downtown Plaza is identified as a strategic retail asset in this plan. The Downtown Plaza is currently undergoing major redevelopment as a new sports arena and mixed use development. Several waterfront areas, including Old Sacramento and Jibboom Street are identified for waterfront development opportunities.

Major employers in Sacramento include the following:

- Government Agencies (including California Air Resources Board, Caltrans, Disabled America Veterans, Employment Development Department, Environmental Protection agency, Municipal Services Agency, Water Resources Department, etc.)

- California State University, Sacramento
- Corrections Department
- Sacramento Regional Transit
- Sutter Memorial Hospital and UC Davis Medical Center
- Sacramento Bee
- SMUD

2.4.1.2 City of West Sacramento

The largest industry sectors in West Sacramento include transportation and warehousing (approximately 4,100 jobs), wholesale trade (approximately 3,100 jobs), retail trade (approximately 2,700 jobs), and manufacturing (approximately 2,100 jobs) (City of West Sacramento 2012).

Major employers in West Sacramento include Raley's, Tony's Fine Foods, United Parcel Service, Norcal Beverage, Beaulieu of America, Dennis Blazona Construction, Siemens Healthcare Diagnostics, FEDEX Freight, Capital Express Lines, Clark Pacific, and Ikea (City of West Sacramento 2012).

Chapter 3 Impacts

This chapter presents the findings of an evaluation of project-related effects on land use, growth, social characteristics (including environmental justice concerns), acquisition/ displacement/ relocation, and economic activity within the study area. Cumulative impacts of the project also are addressed.

3.1 Land Use

Land use impacts evaluated in the following sections include conflicts with existing and planned land uses; consistency with the applicable local planning documents, and impacts on parklands.

3.1.1 Consistency and Compatibility with Existing and Planned Land Uses

In general, the project would involve constructing a new bridge over the Sacramento River to replace the existing I Street Bridge vehicle crossing. Among its key purposes, the new bridge is intended to improve the connectivity to, and accessibility of, businesses, recreational areas, and new or redevelopment opportunity sites located in the urban core of Sacramento and West Sacramento. The project would require acquisitions of land from adjacent parcels, which would displace existing uses. Removal of these land uses, which include strips of recreational and residential use, would not significantly alter the overall land use make-up of the study area. The changes in land use would be consistent and compatible with existing land uses. Acquisitions and relocations are discussed in more detail in section 3.2.3.

3.1.2 Consistency with State, Regional, and Local Plans and Programs

The following sections assess the project's consistency with plans and policies adopted by the City of Sacramento, and the City of West Sacramento. Only policies with direct relevance to the project were included in the consistency analysis.

3.1.2.1 City of Sacramento General Plan

The *City of Sacramento General Plan 2035* was reviewed to identify policies relevant to the project. The project's consistency with relevant policies is discussed below.

Mobility Element

Goal M 1.1 Comprehensive Transportation System. Provide a transportation system that is effectively planned, managed, operated, and maintained.

Policy M 1.1.2 Travel System. The City shall manage the travel system to ensure safe operating conditions. (SO)

Policy M 1.1.4 Facilities and Infrastructure. The City shall effectively operate and maintain transportation facilities and infrastructure to preserve the quality of the system. (SO)

The purpose of and need for the project is to replace the deficient I Street Bridge with a new bridge, which would enhance the safety of the crossing. The project is consistent with these policies.

Goal M 1.2 Multimodal System. Provide expanded transportation choices to improve the ability to travel efficiently and safely to destinations throughout the city and region.

Policy M 1.2.1 Multimodal Choices. The City shall promote development of an integrated, multi-modal transportation system that offers attractive choices among modes including pedestrianways, public transportation, roadways, bikeways, rail, waterways, and aviation and reduces air pollution and greenhouse gas emissions. (MPSP/SO)

Policy M 1.2.3 Multimodal Access. The City shall promote the provision of multimodal access to activity centers such as commercial centers and corridors, employment centers, transit stops/stations, airports, schools, parks, recreation areas, and tourist attractions. (MPSP/SO)

Goal M 1.3 Barrier Removal. Improve system connectivity by removing barriers to travel.

Policy M 1.3.3 M 1.3.3 Eliminate Gaps. The City shall eliminate "gaps" in roadways, bikeways, and pedestrian networks.

a. The City shall construct new multi-modal crossings of the Sacramento and American Rivers.
b. The City shall plan and seek funding to construct grade-separated crossings of freeways, rail lines, canals, creeks, and other barriers to improve connectivity.
c. The City shall construct new bikeways and pedestrianways in existing neighborhoods to improve connectivity. (MPSP/SO)

Policy M 1.3.6 Multi-Jurisdictional Transportation Corridors. The City shall work with adjacent jurisdictions to identify existing and future transportation corridors that should be linked across jurisdictional boundaries so that sufficient right-of-way may be preserved. (IGC)

Goal M 2.1 Integrated Pedestrian System. Design a universally accessible, safe, convenient, and integrated pedestrian system that promotes walking.

Policy M 2.1.2 Sidewalk Design. The City shall require that sidewalks wherever possible be developed at sufficient width to accommodate pedestrians including the disabled; a buffer separating pedestrians from the street and curbside parking; amenities; and allow for outdoor uses such as cafes. (MPSP)

Policy M 2.1.5 Continuous Network. The City shall provide a continuous pedestrian network in existing and new neighborhoods that facilitates convenient pedestrian travel free of major impediments and obstacles. (MPSP)

Policy M 2.1.12 Safe Sidewalks. The City shall develop safe and convenient pedestrianways that are universally accessible, adequately illuminated, and properly designed to reduce conflicts between motor vehicles and pedestrians. (RDR)

Goal M 3.1 Safe, Comprehensive, and Integrated Transit System. Create and maintain a safe, comprehensive, and integrated transit system as an essential component of a vibrant transportation system.

Policy M 3.1.14 Streetcar Facilities. The City shall support the development of streetcar lines in the Central City and other multi-modal districts. (MPSP)

Goal M 4.1 Roadway System. Create a roadway system that will ensure the safe and efficient movement of people, goods, and services that supports livable communities and reduces air pollution and greenhouse gas emissions.

Policy M 4.1.5 Bridge Crossings. The City shall continue to work with adjacent jurisdictions to establish the appropriate responsibilities to fund, evaluate, plan, design, construct, and maintain new river crossings. (IGC)

Goal M 4.2 Complete Streets. Provide complete streets that balance the diverse needs of users of the public right-of-way.

Policy M 4.2.4 Pedestrian and Bicycle Facilities on Bridges. The City shall identify existing and new bridges that can be built, widened, or restriped to add pedestrian and/or bicycle facilities. (MPSP)

Goal M 5.1 Integrated Bicycle System. Create and maintain a safe, comprehensive, and integrated bicycle system and support facilities throughout the city that encourage bicycling that is accessible to all.

Policy M 5.1.1 Bikeway Master Plan. The City shall maintain and implement a Bikeway Master Plan that carries out the goals and policies of the General Plan. All new development shall be consistent with the applicable provisions of the Bikeway Master Plan. (MPSP)

The project represents collaboration between the Cities of Sacramento and West Sacramento and Caltrans to enhance the roadway system and multi-modal opportunities in the study area. The project will improve connectivity and accessibility between the two cities, as well as improve bicycle and pedestrian facilities. The project is consistent with the goals and policies listed above. The project also would not preclude the future development of a streetcar system as a separate project.

3.1.2.2 Railyards Specific Plan

The *Railyards Specific Plan* (2007) was reviewed to identify policies directly relevant to the project. The project's consistency with relevant policies is discussed below.

Goal S-1: Maximize the use of sustainable development practices in the Plan Area.

Policy S-1.6: Promote the installation of pedestrian and bicycle facilities to encourage walking and bicycling, thereby decreasing dependence on motorized vehicles.

Goal CC-1: Create an intensive mixed-use transit oriented urban environment that will become an integral part of the Central City.

Policy CC-1.3: Require active and public- oriented ground level uses that contribute to the pedestrian environment.

Goal OS-1: Provide a system of parks, open space and recreational facilities that serves the needs of future residents and employees of the Plan Area, and that enhances the overall identity of the Central City and the Railyards.

Policy OS-1.3: Utilize opportunities provided by planned open spaces to provide functional and attractive pedestrian and bicycle connections through the Plan Area and to adjacent open space areas such as the Riverfront.

Goal C-3: Create a walkable street system that extends the unique qualities of downtown neighborhoods gives structure and orientation to the downtown experience and enhances the pedestrian environment.

Policy C-3.3: Create and maintain attractive, functional streetscapes that integrate vehicular traffic, pedestrian, bicycle on-street parking and incorporate traffic calming features.

Policy C-3.4: Enhance the non-vehicular environment by developing streets at a scale that is suitable and attractive for pedestrians and bicyclists.

Goal C-4: Extend and improve the existing system of bicycle circulation in downtown Sacramento that is safe and efficient.

Policy C-4.1: Provide bicycle connections to improve circulation.

Policy C-4.2: Provide both on-street and off-street bikeways that provide connectivity within the development and connect to existing and planned bikeways along the Plan Area boundary.

Goal C-5: Create and reinforce safe and efficient pedestrian connections within the Plan Area and in relation to surrounding districts.

Policy C-5.1: Extend pedestrian connections from the downtown area into the Plan Area, as well as Old Sacramento, the Riverfront and the Richards Boulevard area.

Policy C-5.3: Provide safe pedestrian linkages to public spaces, such as schools, transit facilities, riverfront, parks and plazas.

The *Railyards Specific Plan* was developed prior to the decision to replace the existing I Street Bridge with a new bridge. This was a key factor in developing design alternatives for the new I Street Bridge because the Plan area network has a high priority placed on creating a street system that accommodates walking and bicycling. The project will improve connectivity and accessibility of bicycle and pedestrian facilities. The project is consistent with the goals and policies listed above.

3.1.2.3 River District Specific Plan

The *River District Specific Plan* (2011) was reviewed to identify policies directly relevant to the project. The project's consistency with relevant policies is discussed below.

Circulation

Goal C1: Maximize vehicle and pedestrian/bicycle connections within and between the River District and surrounding neighborhoods.

Policy C1b: Improve the design of major streets including North 16th Street, North 12th Street, North 7th Street, Jibboom Street and Richards Boulevard to enhance walkability while moving traffic as smoothly as possible through the District.

Goal C6: Provide pedestrian and bicycle paths, lanes and routes suitable for recreational and commuting purposes.

Policy C6a: Ensure bicycle and pedestrian trails and routes provide seamless connections within and beyond the River District.

Policy C6d: Improve and increase access to and along the rivers for bicycles and pedestrians.

The project will improve connectivity and accessibility of bicycle and pedestrian facilities. The project is consistent with the goals and policies listed above.

3.1.2.4 Sacramento River Parkway Plan

The *Sacramento River Parkway Plan* (1975, Updated 1997) was reviewed to identify policies relevant to the project. The project's consistency with relevant policies is discussed below.

General Policies

Policy G3. There should be close coordination among all public jurisdictions, including, but not limited to the City of Sacramento, the County of Sacramento, Yolo County, the City West Sacramento, and the State Lands Commission in the planning and development of the Sacramento River resources.

Policy G7. Land adjacent to the Parkway shall be protected from injurious or incompatible elements associated with Parkway land uses.

The project involves acquisition of approximately 1.246 acres of the Sacramento River Parkway. The project is a collaboration between the Cities of Sacramento and West Sacramento and Caltrans to construct an improved bridge, which will improve accessibility to the Sacramento River Parkway. The acquisition of 1.246 acre does not represent a significant portion of the parkway, and does not preclude the use of the recreational areas.

3.1.2.5 The City of Sacramento Pedestrian Master Plan (2006)

The City of Sacramento Pedestrian Master Plan is a comprehensive vision for improving pedestrian conditions over the next twenty years. The Plan includes a framework for creating an improved pedestrian environment. The project's consistency with relevant goals and policies are discussed below.

Goal 3: Provide crossings that are convenient and comfortable for pedestrians to use.

Policy. Provide connections over barriers such as railroads, waterways, and freeways.

The project replaces the I Street Bridge with a new bridge that includes improved and pedestrian facilities. It will enhance accessibility for pedestrians and bicyclists traveling over the Sacramento River between the two cities, as well as contribute to the walkability of the riverfront. The project is consistent with the goals and policies listed above.

3.1.2.6 2010 Sacramento City/County Bikeway Master Plan

The *2010 Sacramento City/County Bikeway Master Plan* was developed to serve the recreational and transportation needs of the public. The Plan includes all of Sacramento County which consists of 997 square miles and 3,887 miles of public roads. The following goals and policies relating to community impacts are listed below.

The Bikeway Master Plan Goal: To develop a comprehensive updated Sacramento City/County Bikeways Master Plan which will meet the needs of the bicyclists.

Objective: Coordination. To develop and maintain a coordinated approach by City/County and other agencies to implement the plan as funding becomes available or as development occurs.

Policy (1): Integrate efforts of planning, recreation, public works, and other departments of city and county government and other agencies that are involved in planning, construction or operational elements of the bikeway system.

Objective: Safety and Security. To achieve the highest possible level of safety and security for cyclists.

Policy (1): Provide a network of safe and convenient bikeways.

Objective: Aesthetics. To develop a bikeway system which incorporates aesthetics and the historical characteristics of the Sacramento area.

Policy (1) Bikeways should take full advantage of the beauty and natural features of the Sacramento area by blending with the terrain and topography.

Objective: Implementation. To take necessary actions to implement the preceding Sections 1 thru 5.

Policy (5) At the time of new street construction, pavement overlays, or seal coat operations, all bikeways within the project limits as detailed in this master plan shall be implemented.

The goal of the Plan is to develop a comprehensive and integrated system which will meet the needs of all bicyclists. The proposed project seeks to improve accessibility to bicycle and pedestrian access across the Sacramento River, and is consistent with the policies listed above.

3.1.2.7 City of West Sacramento General Plan

The *City of West Sacramento General Plan* was reviewed to identify policies directly relevant to the project. The project's consistency with relevant policies is discussed below.

> Recreational and Cultural Resources Element
>
> **Goal E: To provide a network of pedestrian and bicycle pathways connecting parks and open space areas with other destination points within and beyond the city of West Sacramento.**
>
> Policy 5. The City shall coordinate with SACOG and surrounding jurisdictions to ensure that bicycle pathways within the city connect with existing and planned facilities outside the city
>
> Transportation and Circulation Element
>
> **Goal A: To create and maintain a roadway network which will ensure the safe and efficient movement of people and goods throughout the city.**
>
> Policy 13. The City shall work with Caltrans and the City of Sacramento in improving the pedestrian and traffic-carrying capacity of the Tower Bridge and the I-Street Bridge, and in the development of future bridges.
>
> **Goal G: To promote pedestrian and bicycle travel as alternatives to automobile use.**
>
> Policy 8. All new bridge crossings shall include bicycle and pedestrian pathways.
>
> Urban Structure and Design Element
>
> **Goal B: To enhance the relationship between the City and the Sacramento River**.
>
> Policy 6. The City shall promote the enhancement of the areas where the "I" Street and Tower Bridges meet the riverfront to create strong, positive, and memorable entryways into West Sacramento and to reinforce the historical significance of these bridges.

The project replaces the I Street Bridge with a new bridge that includes improved bicycle and pedestrian facilities. It will enhance accessibility between the two cities, as well as contribute to the development of both riverfronts. The project is consistent with the goals and policies listed above.

3.1.2.8 Washington Specific Plan

The *Washington Specific Plan* (1996) was reviewed to identify policies relevant to the project. The project's consistency with relevant policies is discussed below.

Transportation and Circulation

Goal 3A. To create and maintain a roadway network in the Washington Plan Area that will ensure the safe and efficient movement of people and goods within and through the Plan Area.

Policy 3.A.3. The City shall work with Caltrans and the City of Sacramento in improving the traffic and pedestrian carrying capacity of the Tower Bridge and the I-Street Bridge and to provide more direct connections from these bridges into the Washington Plan Area.

Goal 3C. To encourage communication and cooperation within the community, with adjacent jurisdictions, and with state and federal agencies concerning transportation issues affecting the Washington Plan Area.

Policy 3.C.2. The City should continue to cooperate with the City of Sacramento to establish roadway, pathway, and river transportation links between Washington Plan Area and Sacramento.

Goal 6.B. To enhance the relationship between the Washington Plan Area and the Sacramento River.

The project will improve access for all forms of transportation across the Sacramento River. It also provides an enhanced connection between the Washington Plan Area and Sacramento. The project is consistent with the goals and policies listed above.

3.1.2.9 Washington Realized-Sustainable Community Strategy

The *Washington Realized Sustainable Community Strategy* (City of West Sacramento 2015) was reviewed for consistency with the proposed project. An overall goal of this document is to focus on transit-oriented development. The proposed project is aligned with this goal because it would improve local connectivity and access to local businesses, including the Washington neighborhood and adjacent riverfront recreation and development. The proposed project does not preclude future transit developments, such as the streetcar. It also improves bicycle and pedestrian facilities across the bridge, which are all a part of the Washington Realized transit-oriented development strategy. Washington Realized makes recommendations for future land use and transportation strategies and policies that could be included in an updated General Plan or a Specific Plan. Washington Realized currently recommends a roadway cross-section for C Street that is different than what is proposed by the proposed project. Should the cross-section proposed by Washington Realized become a policy of West Sacramento in the future, the I Street Bridge project would potentially conflict with that future, not yet adopted, policy. However, it is not yet known what recommendations will ultimately be adopted.

3.1.2.10 West Sacramento Bicycle, Pedestrian, and Trails Master Plan

The *West Sacramento Bicycle, Pedestrian, and Trails Master Plan* (Fehr & Peers 2013) was reviewed to identify policies directly relevant to the project. In addition to the City's General Plan policies, the Master Plan identifies specific policies relating to Bicycle, Pedestrian, and Trails. The project's consistency with these relevant policies is discussed below.

> Policy 2. A continuous and interconnected system of bikeways and walkways that provide safe and convenient travel to key destinations.
>
> Policy 4. A transportation system that is safe for bicycling and walking such that bicyclist- and pedestrian vehicle collision rates decrease from 2013 levels

The project improves bicycle and pedestrian access across the Sacramento River, and is consistent with the policies listed above.

3.1.3 Parks and Recreational Facilities

As stated in Chapter 2, multiple parks, trails, and open space areas are located throughout the study area, particularly along the riverfront. This section discusses the parks and trails adjacent to proposed improvements with the potential to be directly or indirectly affected by project construction or operation. Other parks and recreational facilities in the study area are not anticipated to experience changes in access or use as a result of the project. Public park and recreational facilities are also shown in Table 3-2 below, in Section 3.2.3, Acquisitions and Relocations, and analyzed in detail in the *Section 4(f) Report* prepared for this project. The complete Section 4(f) evaluation can be found in the *Draft Section 4(f) Report* (ICF International 2015a).

The project would result in both temporary and permanent impacts to the riverfront parks in both the Sacramento and West Sacramento portions of the study area. In Sacramento, approximately 2.155 acres would be acquired from the Sacramento River Parkway (parcels 002-010-023 and 001-210-018). Both of these parcels are owned by the State of California. The Sacramento River Parkway Trail is routed through these two parcels along the river and would require a detour during construction. No acquisitions would be required at Matsui Waterfront Park. 1.123 acres would be acquired from a future park site in Sacramento (Park Site CC6). Construction of the project with either of the City of Sacramento Roadway Design alternatives would result in the same amount of right-of-way acquisitions.

In West Sacramento under City of West Sacramento Residential Access Alternative 1, approximately 0.989 acre would be acquired from the southern portion of Broderick Boat Ramp. Under City of West Sacramento Residential Access Alternative 2, approximately 0.135 acre would be acquired from the park. While the City of West Sacramento Residential Access Alternative 1 would have the larger impact on this park, under both alternatives the area that would be acquired is at the southern portion of the park, away from the boat ramp and other developed facilities. The proposed River Walk Park area north of the existing I Street Bridge would also be affected. Under both City of West Sacramento Residential Access Alternatives, 3.083 acres would be acquired from this proposed park site (parcels 010-102-004, 010-102-003, 010-102-002, 010-102-010, and 010-372-010).

Overall, the parkland acquisitions required for the project would be minor and would not affect the overall viability of the parks and recreational facilities in the community. The project would result in an acquisition from the Sacramento River Parkway, but it would not significantly alter the recreational opportunities in that area, which mainly include use of the Sacramento River

Parkway Trail. The trail would be detoured for two years, and then would be restored within the Sacramento River Parkway. As stated above, the project would require temporary re-routing of the Sacramento River Parkway trail along Jibboom Street during construction. The temporary alignment for the trail would follow the temporary Jibboom Street alignment south of Railyards Boulevard. Northbound cyclists and pedestrians would then follow a detour north along Bercut Drive to Richards Boulevard, where they could connect back to the Parkway on the west side of I-5. The detour would be in place for approximately 2 years.

3.1.4 Growth Inducement

This section discusses the potential growth inducement impacts of the project on the areas most likely to be affected, which are anticipated to be the Cities of Sacramento and West Sacramento.

3.1.4.1 NEPA and CEQA Basis for Analysis of Growth Inducement Impacts

The findings of the growth analysis contained in this report will be used as the basis for the assessment of growth inducement effects in the project's NEPA/CEQA environmental document. Therefore, NEPA and CEQA considerations are relevant to the growth analysis presented in this section.

The President's Council on Environmental Quality (CEQ) regulations, which implement NEPA, require evaluation of the potential environmental consequences of all proposed federal activities and programs. This provision includes a requirement to examine indirect consequences that may occur in areas beyond the immediate influence of a proposed action at some time in the future. The CEQ regulations refer to these consequences as *secondary impacts* (40 Code of Federal Regulations [CFR] 1508.8). Secondary impacts may include changes in land use, economic vitality, and population density—all of which are elements of growth.

CEQA also requires analysis of a project's potential to induce growth. The State CEQA Guidelines (Section 15126.2[d]) require that environmental documents:

> [d]iscuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristics of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

Based on this guidance, growth inducement impacts would result from a project that would directly or indirectly foster (i.e., promote or encourage) additional economic or population growth or construction of additional housing. Fostering of growth can occur when an obstacle to growth is removed (e.g., when expansion of infrastructure resolves growth-constraining capacity problems). For an analysis to reach the conclusion that a project is growth-inducing, as defined

by CEQA, it must find that a project would foster additional growth in economic activity, population, or housing.

If the analysis determines that a project is growth-inducing, the next question is whether that growth may cause adverse effects on the environment. Environmental effects resulting from induced growth fit the CEQA definition of *indirect effects* in State CEQA Guidelines Section 15358(a)(2). These indirect or secondary effects of growth may result in significant environmental impacts. CEQA does not require that an environmental impact report (EIR) prepared for a project speculate unduly about the precise location and site-specific characteristics of significant indirect effects caused by induced growth, but a good faith effort is required to disclose what is feasible to assess. Potential secondary effects of growth could include consequences that result from growth fostered by a project (e.g., conversion of open space to developed uses, increased demand on community and public services and infrastructure, increased traffic and noise, degradation of air and water quality, or degradation or loss of plant and wildlife habitat).

If significant indirect environmental effects of growth may occur, the final question is whether those effects already have been considered and mitigated, or overridden if unavoidable, in a completed CEQA process. If the induced growth is consistent with an approved general plan or community plan for the area, and if a CEQA document on that plan adequately addresses the effects of growth, the environmental effects of growth induced by the project already have been evaluated. In this circumstance, the EIR for a project may refer to the completed CEQA document for the impact analysis and does need not reevaluate previously identified impacts. A project that would induce growth not consistent with an adopted general plan or community plan could indirectly cause additional significant environmental impacts beyond those evaluated in the earlier CEQA document on the plan.

Growth inducement may constitute an adverse impact if the growth is not consistent with or accommodated by the land use plans and growth management policies for the affected area. Local land use plans provide development patterns and growth policies that allow orderly expansion of urban development that is supported by adequate urban public services (e.g., water supply, roadway infrastructure, and sewer service). A project that would induce *disorderly growth* (i.e., conflict with the local land use plans) could indirectly cause additional adverse environmental impacts and other public service impacts, sometimes referred to as *secondary impacts*. Therefore, to assess whether a growth-inducing project would result in adverse secondary effects, it is important to assess the degree to which the growth accommodated by the project would be consistent with applicable land use plans.

A transportation improvement, such as the proposed project, would be considered growth-inducing if it would cause economic or population increases greater than what is planned by the local agency without the project. If the improvement would cause new development and an influx of residents, as well as increase the economic strength in an area, it may be growth-inducing. It is not assumed that growth in an area is fundamentally beneficial, detrimental, or of little significance to the environment.

The decision to allow potentially induced growth is the subject of separate decision making by the lead agency responsible for allowing such projects to move forward. Because the decision to

allow growth is subject to separate discretionary decision making, and because such decision making itself is subject to CEQA, the analysis of growth inducement effects is not intended to determine site-specific environmental impacts or specific mitigation for the potentially induced growth. Rather, the discussion is intended to disclose the potential for environmental effects to occur more generally, such that decision makers are aware that additional environmental effects are possible if growth-inducing projects are approved. The decision of whether impacts do occur, their extent, and the ability to mitigate them is appropriately left to consideration by the agency responsible for approving such projects, at such times as complete applications for development are submitted.

3.1.4.2 Analysis of Growth Inducement Impacts

Growth rates and patterns are influenced by various local, regional, and national forces that reflect ongoing social, economic, and technological changes. Ultimately, the amount and location of population growth and economic development that occurs in a specific area are controlled largely by local governments through zoning, land use plans and policies, and decisions regarding development applications. Local government and other regional, state, and federal agencies and tribes also make decisions about infrastructure (e.g., roads, water facilities, and sewage facilities) that may influence growth rates and the location of future development.

Transportation infrastructure is one component of the overall infrastructure that may serve to accommodate planned growth. This infrastructure also may serve to hasten or shift planned growth, or to encourage and intensify unplanned growth in an area. Transportation projects may induce growth when they directly or indirectly promote, shift, or intensify planned growth or encourage unplanned growth in a community or region. An example of a growth-inducing transportation project includes construction of a new roadway through an undeveloped area, which could open access to a new area and promote unplanned growth.

To determine the potential for growth-related impacts associated with the project, a first-cut screening was performed in accordance with the *Guidance for Preparers of Growth-Related, Indirect Impact Analyses* (referred to in the remainder of this section as *the Guidance document*) (California Department of Transportation 2006). The interrelated screening factors (accessibility, growth pressure, project type, and project location) discussed in Chapter 5 and summarized in Figure 5-2 of *the Guidance document* were considered. The results of this analysis are detailed below.

- *Does the project have the potential to change accessibility?*

In terms of accessibility, the project would improve accessibility between Sacramento and West Sacramento by replacing the existing I Street Bridge with an improved bridge. The existing I Street Bridge does not comply with current design and traffic operation standards for vehicles, bicycles, or pedestrians. The width of the existing I Street Bridge is not sufficient to provide adequate traffic operations, bicycle lanes, adequate and ADA compliant pedestrian facilities or public transit across the bridge. Improving the bridge and adjacent intersections would improve access throughout the project area, which would benefit the surrounding residents of Sacramento and West Sacramento.

- *Is the project-related growth reasonably foreseeable?*

In terms of growth pressure, the extent to which the project would induce growth in the project area depends largely on the strength of local planning and growth management mechanisms, including adhering to adopted growth boundaries, maintaining existing zoning restrictions and land use designations, and implementing farmland and floodplain protection policies. The Cities of Sacramento and West Sacramento have provided land use designations to guide future growth in the study area; and new development must adhere to these land use designations, per the rules and regulations of the relevant cities. Adherence to these restrictions reduces pressure for unplanned development by making adequate quantities of land available for development in locations that best serve the policy goals of the relevant cities. Given the coordinated growth control mechanisms in place, the project is unlikely to substantially encourage unplanned development in the project area, or to shift or hasten planned growth in the study area. Growth-related impacts of the project related to growth pressure would be minimal to none.

In terms of project type, the project would construct a new two-lane crossing for vehicles to the north of the existing crossing that would connect to Railyards Boulevard instead of I Street on the Sacramento side. The new crossing would include facilities for bicycles and pedestrians. The two-lanes of vehicular travel on the existing bridge would be relocated to the new bridge and the existing I Street Bridge would remain for railroad use only. As described in *the Guidance document,* projects that do not increase roadway capacity are not typically considered likely to cause growth-related impacts.

In terms of project location, the project is located in a built-up urban area. As detailed in *the Guidance document,* transportation projects in urban areas are less likely to cause growth-related impacts because the land uses are generally build-out. Presently, the study area is largely built out. Most of the development planned for the study area is infill such as within the Railyards and Washington Specific Plan areas. The Railyards Specific Plan area is planned for mixed use development. Roadway and other infrastructure in currently under construction. Some vacant parcels in West Sacramento are already planned for future development under the Washington Specific plan. As stated in Chapter 2, growth is expected in the surrounding region. This growth would not be attributable to, or otherwise influenced by, the project.

Based on the first-cut screening analysis detailed above, the project would not be growth-inducing, and further analysis of its potential for growth inducement is not necessary.

3.2 Community Impacts

This section addresses the community impacts of the project, including effects on community character and cohesion, community facilities, relocations, and environmental justice.

3.2.1 Community Character and Cohesion

According to Caltrans guidelines for conducting Community Impact Assessments (California Department of Transportation 2011), *community cohesion* is the degree to which residents have a "sense of belonging" to their neighborhood; a level of commitment of the residents to the community; or a strong attachment to neighbors, groups, or institutions—usually because of

continued association over time. Communities often are delineated by physical barriers such as major roadways or large open space areas.

Cohesive communities are indicated by specific social characteristics such as long average lengths of residency, home ownership, frequent personal contact, ethnic homogeneity, high levels of community activity, and shared goals. Transportation projects may divide cohesive neighborhoods when the projects act as physical barriers or are perceived by residents as psychological barriers. A transportation project perceived as a physical or psychological barrier may isolate one portion of a homogeneous neighborhood.

The study area is divided east/west by the Sacramento River. The Sacramento portion of the study area is further divided by I-5, and due to the urban and industrial nature of the Downtown Sacramento area, this portion of the project area does not possess a high level of community cohesion. The West Sacramento portion of the project area is divided by the UPRR tracks. West Sacramento has more of a small-town sense, and the established neighborhood in the northwest portion of the study area, with associated schools, parks, and facilities makes for a higher level of community cohesion.

The affected roadways in the study area, including I Street in Sacramento and C Street in West Sacramento, serve as primary transportation routes for commuters and patrons of the local businesses and shopping areas. I Street and C Street also serve as a primary transportation route between Sacramento and West Sacramento. During the construction period, roadways would remain open with unrestricted travel during hours of non-construction activities. Travelers may experience delays during periods of active construction that would require temporary lane closures. These delays could discourage some travelers from using these access routes, but lane closures would be temporary, and implementation of the project's Traffic Management Plan (TMP) would ensure that access to adjacent properties would be provided during construction and that delays would be minimized as much as possible.

The project would not construct any new structures or roadways that would significantly alter the divisions already existing in the community or that could further divide existing communities. The connectivity provided by the existing I Street Bridge would be maintained with the new bridge. The transportation infrastructure being constructed in the Railyards Specific Plan area would connect the new bridge location to downtown Sacramento and the access point in West Sacramento would not change. Also, the new bridge would contain bicycle and pedestrian facilities that would improve bicycle and pedestrian connectivity between the cities.

Though traffic patterns would change slightly on local streets there is little potential for cut-through traffic to disrupt existing neighborhoods or community areas. Although the project could cause traffic delays in the study area during active construction periods, cut-through traffic routes that could avoid these delays are not readily available. Thus, no negative effects on community cohesion would be caused by cut-through traffic associated with the project.

3.2.2 Community Facilities

This section addresses the impacts of the project on schools, health care facilities, and alternative transportation in the study area.

3.2.2.1 Schools

The project would not require acquisition or displacement of any school sites in the study area. As discussed in Chapter 2, there are several schools within the study area. However, these schools are not close enough that they would experience temporary noise impacts associated with project construction. It is not anticipated that school bus travel and individual motorist travel to and from local schools would be affected by the project because construction would be concentrated around the new bridge, and residents typically would not be crossing the river to get to/from school, but rather would attend schools in their respective cities.

3.2.2.2 Access, Circulation and Parking

The project would change access and circulation on local roads in the immediate vicinity of the project for motorists, pedestrians, and bicyclists traveling between Sacramento and West Sacramento. Both temporary and permanent changes would occur. During construction, motor vehicles would continue to use the existing facilities in both cities to access the existing I Street Bridge and cross the Sacramento River. In Sacramento, proposed temporary closures of Jibboom Street north of Railyards Boulevard and a temporary access road and detour would be in place for up to 2 years to maintain local access to the Jibboom Street viaduct while the bridge is being built. This temporary change in access and could cause delays, especially when first implemented.

During construction, pedestrians and bicyclists would also continue to use existing facilities in both cities to access the existing I Street Bridge and cross the Sacramento River. A temporary detour of the Sacramento River Parkway trail would be in place for up to 2 years but the connection between the Sacramento River Parkway and the American River Parkway trails would be maintained. Access to the River Walk Park trail south of the existing I Street bridge would not be affected.

Currently, motorists traveling between Sacramento and West Sacramento north of the Tower Bridge cross the Sacramento River on the existing I Street Bridge, which is accessed by I Street in Sacramento and C Street in West Sacramento. With the project, the new I Street Bridge would be accessed from Railyards Boulevard in Sacramento. In West Sacramento, motorists would continue to access the bridge from C Street. Motorists coming from downtown Sacramento would access Railyards Boulevard from 5th Street or other connectors. For motorists traveling from the downtown Sacramento area, this route is less than one mile longer than the current I Street route. For motorists traveling from areas north and northeast of the Railyards property, the new route would be shorter than the current route from I Street.

City of Sacramento Roadway Design Alternatives 1 and 2 would create different intersection experiences at the Railyards Boulevard/Jibboom Street/Bercut Drive intersection (signalized versus roundabout) but would result in only minor operational differences.

In West Sacramento, the roadway changes proposed for the C Street connection to the new bridge would cut off access to four residential parcels and one multifamily parcel located along 2nd Street, north of C Street. City of West Sacramento Residential Access Alternative 1 would construct a new connection to C Street, approximately 150 feet east of the C Street/3rd Street intersection, that would extend north to B Street and then ultimately connect to the 3rd Street/B Street intersection. City of West Sacramento Residential Access Alternative 2 would connect to the same location at C Street as Alternative 1, approximately 150 feet east of the C Street/3rd Street intersection, but would continue north approximately 300 feet, then make a 90-degree left turn, and connect to 3rd Street approximately 300 feet north of C Street. While this would change the local access route, it would not require a substantial detour or change in route (change is less than 500 feet).

The project would modify access and circulation on the two Class I trails that parallel the river by adding trail-to-roadway connections to the new bridge crossing that are not present in the existing bridge design. The Sacramento River Parkway would have a grade separation that would allow users to either pass under the new roadway and new bridge, or continue up to the new roadway and travel either west or east. In West Sacramento, the proposed levee maintenance road would serve as an extension to the Class I River Walk Park trail. Similar to the trail improvements proposed for the Sacramento River Parkway, the trail would be grade-separated under the proposed bridge structure and also provide connections to east- and west-bound C Street from the trail.

Once the new I Street Bridge is in place, the route for pedestrian and bicyclists traveling between the downtown Sacramento area and C Street in West Sacramento would be slightly longer than the current route (approximately 0.2 miles). For pedestrians and bicyclists traveling to and from the area north of the Railyards property, the route would be shorter.

3.2.3 Acquisitions and Relocations

Implementation of the proposed project would require the acquisition of private property, including residences and parkland (parkland impacts are discussed above in section 3.1.3). Project impacts include both full and partial acquisitions, which may displace or alter existing uses. Full acquisition of a property occurs if the entire parcel is within the footprint (right-of-way) of an alternative or if any portion of a building is located within the footprint of the alternative. Full acquisitions also occur when the property is needed for right-of-way or levee fee/easements and results in an uneconomic remnant. Partial acquisition of a property occurs if any part of a parcel is within the footprint (right-of-way) of the alternative but does not require the displacement of the structures on the property. These impacts range from a sliver or edge of a parcel within the proposed right-of-way to substantial portions that fall short of entire displacement. Table 3-2 shows the proposed acquisitions. Because there are no differences in acquisition impacts proposed as part of the City of Sacramento roadway design alternatives, difference in acquisitions needed for the project are broken down by the West Sacramento residential access alternatives.

Table 3-2. Proposed Parcel Acquisitions

Parcel Number	Description	Ownership	Proposed Project with West Sacramento Residential Access Alternative 1* (acres)	Proposed Project with West Sacramento Residential Access Alternative 2* (acres)

*There are no differences in acreage impacts as a result of the City of Sacramento roadway design alternatives.

3.2.3.1 Proposed Project with West Sacramento Residential Access Alternative 1

As shown in Table 3-2, construction of the proposed project with West Sacramento Residential Access Alternative 1 would require right-of-way acquisitions from 25 individual parcels and removal a multi-family residence (APN 010-101-013). Acquisition and structure removal on APN 010-101-013 would affect up to four individual apartments. In addition, West Sacramento Residential Access Alternative 1 would require 0.415 more acre of acquisition from Broderick Boat Ramp (parcel 010-103-001) and 0.438 acre from parcel 010-103-002 than West Sacramento Residential Access Alternative 2.

3.2.3.2 Proposed Project with West Sacramento Residential Access Alternative 2

Construction of the proposed project with West Sacramento Residential Access Alternative 2 would require right-of-way acquisition from 23 individual parcels. One individual apartment in the apartment building on APN 010-101-013 would be affected. A single family residence, located on APN 010-101-004, would be removed.

3.2.4 Environmental Justice

The project is being developed in accordance with the Civil Rights Act of 1964, as amended; the Uniform Relocation and Assistance and Real Property Acquisition Policies Act of 1970, as amended; and Executive Order 12898 (Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations). Executive Order 12898 requires each federal agency to take the appropriate and necessary steps to identify and address disproportionately high and adverse human health and environmental effects of its programs, policies, and activities on minority and low-income populations.

Environmental justice refers to the fair treatment of people of all races, cultures, and incomes with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. The CEQ's *Environmental Justice: Guidance under the National Environmental Policy Act* (1997) indicates that environmental justice concerns may arise from impacts on the natural or physical environment, such as human health or ecological impacts on minority and low-income populations, or from related social or economic impacts.

For adverse environmental justice effects to result from the project, two conditions need to exist. First, minority or low-income populations need to reside in parts of the study area that would be adversely affected by the project. Second, any adverse impacts would need to fall disproportionately on minority or low-income populations, rather than proportionately on all populations affected by the project.

Once minority and/or low-income populations are identified and an environmental justice analysis is required, a determination must be made as to whether there would be a disproportionately high and adverse effect on human health or the environment. This requires comparing the burdens and benefits that would be experienced by environmental justice populations with the burdens and benefits that would be experienced by non–environmental justice populations. U.S. Department of Transportation Order 5610.2(a) defines a *disproportionately high and adverse effect* as one that would meet either characteristic below.

- The adverse effect would be predominantly borne by a minority and/or low-income population.
- The adverse effect suffered by the minority and/or low-income population would be appreciably more severe than the adverse effect suffered by the non-minority and/or non–low-income population.

An analysis of the project based on these criteria is provided below.

As discussed in more detail in Chapter 2 (Table 2-2), several of the census tracts in the study area have higher percentages of minority populations and low-income populations compared to the rest of Sacramento and West Sacramento. Therefore, an environmental justice evaluation is warranted. The block groups with notably low incomes include CT 07.00 BG 1 and CT 53.01 BG 1 in Sacramento, and CT 101.01 BG 4 in West Sacramento. As shown in Figure 2-2, CT 07.00 BG 1 is located in the Downtown Sacramento/Old Sacramento area. This block group is divided by a major freeway, I-5. There is very little residential development in this block group, and no single-family homes. Residents in this block group would live in high-density residential housing, or temporary housing in motels. There is an apartment building at 5th and I Street that offers senior citizen housing. CT 53.01 BG 1 is located in the northeast portion of the study area and is mainly comprised of industrial land uses, including the Sacramento Railyards. There is very little residential development in this block group. The Dos Rios housing project is located in this block group, but it is located over a mile northeast of the project limits. In CT 101.01 BG 4, there is an established neighborhood in between the UPRR tracks and G Street in West Sacramento. This neighborhood consists of older single family residences as well as multi-family complexes. Most of the residents in the study area are located within CT 101 BG 1 and CT 101 BG 3.

3.2.4.1 Adverse Effects on the Overall Population

The technical reports addressing aesthetics/visual resources, air quality, and noise and vibration indicate that some potential adverse effects are expected to result from the project. The impacts identified in these technical reports and the measures to avoid or reduce them are summarized below.

Aesthetics/Visual Resources

As described in the *Draft Visual Impact Assessment* (ICF International 2015b), the visual degradation resulting from project construction activities would be more noticeable in urban areas adjacent to residences and recreation areas than in industrial and commercial areas. However, construction impacts would be temporary, and construction staging areas would be

restored to preproject conditions after construction is completed. Accordingly, impacts resulting from construction of the project are considered less than significant. Mitigation measures identified in Chapter 4 would reduce construction impacts on aesthetics/visual resources.

The project features would generally appear consistent with similar existing features, and the project would not substantially obstruct long-distance views or substantially alter the existing visual character of the study area. Therefore, impacts resulting from operation of the project are considered less than significant. Mitigation measures listed in the *Draft Visual Impact Assessment* (ICF International 2015b) would reduce operational impacts on aesthetics/visual resources.

Air Quality

Construction of the project would generate dust, diesel fumes, and noise during construction periods. Impacts would be shared proportionally by all residents surrounding the study area, not experienced only by the minority residents. Impacts resulting from construction and operation of the project are considered less than significant. Mitigation measures listed in the *Draft Air Quality Study Report* (Terry A. Hayes Associates 2015) would reduce air quality impacts in the study area.

Noise and Vibration

According to the *Draft Noise Study Report* prepared for this Project (ICF International 2015c), no adverse noise impacts are anticipated during construction because construction would be conducted in accordance with provisions in Section 14-8.02, "Noise Control," of the *Caltrans Standard Specifications* and applicable local noise standards. Construction noise would be short term, intermittent, and typically overshadowed by local traffic noise.

According to the *Draft Noise Study Report*, traffic noise levels would increase by up to 5 dB relative to existing conditions, which would not result in a substantial increase in noise levels. In addition, noise barriers are not feasible throughout the study area, as described in the report. No other mitigation is required.

3.2.4.2 Potential Disproportionate and Adverse Effects on Environmental Justice Populations

Temporary visual effects from construction work would be experienced throughout the study area. These effects would be minor and would be borne equally by all communities along the project alignment. Additionally, construction impacts would be temporary, and construction staging areas would be restored to pre-project conditions after construction is completed. Accordingly, no disproportionately high or adverse effects associated with visual changes, air quality, and noise would be experienced by a minority or low-income population.

Environmental Justice Conclusion

In general, impacts resulting from construction would be most noticeable in the areas closest to the project alignment because construction work would create traffic, noise, and dust. However,

the impacts borne by the environmental justice populations of the study area would be similar to and no greater than impacts borne by all populations within the study area. As stated above, minority and low income populations are located in pockets and are not pervasive throughout the study area. Most of the residents in the study area are located in CT 101 BG 1 and CT 101 BG 3, which have incomes more comparable to the respective cities.

For the reasons above and in consideration of the benefits that the project would provide to *all* the minority and low-income residents of the study area by increasing access, the proposed project is not considered to cause disproportionately high and adverse human health and environmental effects on minority and low-income residents of the study area.

All considerations under Title VI of the Civil Rights Act of 1964 and related statutes have been included in this project. Caltrans' commitment to upholding the mandates of Title VI is evidenced by its Title VI Policy Statement, signed by the Director.

3.3 Emergency Services and Utilities

This section addresses the impacts of the project on emergency services, including police, fire protection, and emergency medical services, and on utilities and communications providers.

3.3.1 Police, Fire Protection, and Emergency Medical Services

It is expected that public facilities and emergency service centers in the project vicinity would be minimally affected during construction because the existing I Street Bridge would remain open and functional during construction. During construction, short-term lane closures would be necessary on local streets, as described above in section 3.2.2.3. The following emergency service providers would be notified by the lead agency prior to any road closures.

- Sacramento County Sheriff Department
- Yolo County Sheriff Department
- City of Sacramento Police Department
- City of West Sacramento Police Department
- City of Sacramento Fire Department
- City of West Sacramento Fire Department
- California Highway Patrol
- American Medical Response

As stated in Section 3.2.2.3, access and circulation would change in the study area. Depending on what direction the emergency service is driving to or from, the route could be shorter, or up to about one mile longer. Implementation of a TMP would ensure that construction would not create major delays for emergency service providers. In addition, emergency service providers

would be notified as early as possible in order to plan for lane closures and other delays related to construction activity.

3.3.2 Utilities, Public Services and Communication Providers

A number of public and private utilities would need to be relocated or adjusted to grade as part of the project, including existing water, sewer, gas, electric, and communication facilities within Jibboom Street, Bercut Drive, C Street, and 2nd Street.

Notifying and coordinating with utility providers would ensure that potentially affected utility customers are notified of potential service disruptions before they occur.

3.4 Economic Impacts

3.4.1 Construction-Related Economic Impacts

Construction of the proposed project would have temporary economic effects in the local area and region. One temporary effect would be an increase in economic activity due to project-related spending, including purchases of goods and services required for construction and employment of workers needed for construction. The increased economic activity would prompt secondary economic activity as a portion of the construction-related revenue, and employee compensation is re-spent in sectors throughout the local and regional economy. The extent of the economic impact of construction-related expenditures on the local and regional economy would depend on the proportion of construction expenditures that would occur in the local and regional area and on the residential location of persons employed by construction contractors.

3.4.2 Operation-Related Economic Impacts

It is expected that relocations would take place within the city of West Sacramento, and therefore no impacts to the taxable value of the property in this city is anticipated. The function of the bridge would be to improve local connectivity. It is intended to improve access to local businesses, recreation areas, and new development/redevelopment sites located in the urban core of Sacramento and West Sacramento. Therefore, by improving access and connectivity in the study area, the proposed project is expected to indirectly result in an increase in the taxable value of land in both cities.

3.5 Cumulative Impacts

For purposes of this CIA, cumulative impacts on resources in the general project vicinity may result from closely related projects that add incrementally to the impacts of the proposed project.

Other development projects, such as the Railyards, Township 9, The Bridge District and development along the waterfront in both cities are currently planned and some are under construction. If these projects are constructed concurrently with the proposed project, potentially considerable cumulative impacts could result in traffic delays to motorists, including emergency service providers. However, including a TMP and providing early notification of service providers would reduce these impacts to less than cumulatively considerable levels.

Chapter 4 Avoidance, Minimization, and/or Mitigation Measures

4.1 Measures to Reduce Land Use Impacts

In addition to the measures in the TMP, the following measures are proposed to reduce the adverse socioeconomic impacts that could result from the project. These measures would apply to the proposed project and the design alternatives.

4.1.1 Conflicts with Existing and Planned Land Uses

No potential conflicts with current planned land uses in the study area are anticipated. Therefore, no measures to reduce impacts are proposed.

4.1.2 Direct and Indirect Land Use Impacts

Air quality and aesthetic mitigation and abatement measures should be implemented to reduce the direct and indirect land use impacts of the project. The following measures are from the Air Quality Study Report (Terry A. Hayes Associates 2015), and Visual Impact Report (ICF International 2015c) prepared for the project.

Air Quality Mitigation

- The contractor shall obtain all necessary Sacramento County and Yolo County permits and approvals and shall follow all required County laws and procedures and respect to best management practices, grading and excavation for the proposed project and all construction-related and emission-generating activities.
- Construction of the project shall comply with Sacramento Metropolitan Air Quality Management District (SMAQMD) and Yolo-Solano Air Quality Management District (YSAQMD) Basic Construction Emission Control Practices, Exhaust Control Practices, and Fugitive PM Dust Control Practices.
- Construction activity within The Railyards Specific Plan area shall comply with the mitigation measures contained in the adopted Mitigation Monitoring and Reporting Plan for The Railyards development (City of Sacramento 2007).

Visual Impact Mitigation

- Work with Stakeholders to Determine Bridge Aesthetics. The project proponent will conduct a focused outreach effort and will conduct a public meeting or charrette session with public stakeholders to develop an aesthetic design approach to aid in reducing the visual impact of the proposed bridge. This measure will allow concerned viewers to aid in creating a bridge that is visually appealing to the general public, while balancing the need for increased

circulation access at this location. Affected stakeholders will be able to provide input on the preferred architectural style and coloring of the proposed bridge.

- Implement Project Landscaping. The project proponent will install landscaping where space and safety considerations allow. This will improve the visual quality of the project corridor by improving corridor aesthetics and helping to reduce the apparent scale of new and reconfigured intersections, in addition to replacing some of the vegetation lost through construction. Prior to approval of the roadway design, the City of Sacramento and /or City of West Sacramento project landscape architect will review project designs to ensure that the following elements are implemented in the project landscaping plan.
  - Design and implement low impact development (LID) measures that disperse and reduce runoff by using such features as vegetated buffer strips/medians between paved areas that catch and infiltrate runoff. In addition, pervious paving will be evaluated for use in the proposed project to improve infiltration and to reduce the amount of surface runoff from entering waterways and the storm water system. LID measures will not be used where infiltration could result in adverse environmental effects. LID measures, such as cobbled swales and aggregate mulching, can be used as an aesthetic design element to create an attractive view while reducing water use.
  - Require construction contractors to incorporate native grass and wildflower seed to standard seed mixes, which may be non-native, for erosion control measures that will be applied to all exposed slopes. Wildflowers will provide seasonal interest to areas where trees and shrubs are removed and grasslands are disturbed. Only wildflower and grass species that are native will be incorporated into the seed mix, and under no circumstances will any invasive grass or wildflower plant species be used as any component in any erosion control measures. Species will be chosen that are indigenous to the area and for their appropriateness to the surrounding habitat. For example, upland grass and wildflower species will be chosen for drier, upland areas, and wetter species will be chosen for areas that will receive more moisture. If not appropriate to the surrounding habitat, wildflowers should not be included in the seed mix.
  - Require the species list to include trees, shrubs, and an herbaceous understory of varying heights, as well as both evergreen and deciduous types. Plant variety will increase the effectiveness of the roadside planting areas by providing multiple layers, seasonality, diverse habitat, and reduced susceptibility to disease. Evergreen groundcovers or low-growing plants, such as *Ceanothus* spp., should be used in areas where taller vegetation would potentially cause driving hazards by obscuring site distances. Species used will be native and indigenous to the project area and California. Native plant species can be used to create attractive spaces, high in aesthetic quality, that are not only drought-tolerant but also attract more wildlife than traditional landscape plant palettes. Use of native species promotes a visual character of California that is being lost through development and reliance on non-native ornamental plant species.
  - Use vegetative accents and screening to reduce the perceived scale and mass of the built features, while accentuating the design treatments that will be applied to built features. Special attention should be paid to plant choices near residences to ensure that species chosen are of an appropriate height and rely on evergreen species to provide year-round light screening from nuisance light, if applicable.

  - Under no circumstances will any invasive plant species be used at any location.
  - Plant vegetation within the first 6 months following project completion.
  - Implement an irrigation and maintenance program during the plant establishment period and carried on, as needed, to ensure plant survival. However, design of the landscaping plan will try to maximize the use of planting zones that are water efficient. The design also may incorporate aesthetic features, such as cobbling swales or shallow detention areas, which can reduce or eliminate the need for irrigation in certain areas.
  - If an irrigation system is required, use a smart watering system in areas that are irrigated to evaluate the existing site conditions and plant material against weather conditions to avoid overwatering of such areas. To avoid undue water flows, manage the irrigation system in such a manner that any broken spray heads, pipes, or other components are fixed within 1–2 days, or the zone or system will be shut down until it can be repaired.

- Apply Minimum Lighting Standards. All artificial outdoor lighting and overhead street lighting is to be limited to safety and security requirements and the minimum required for driver safety. Lighting will be designed using Illuminating Engineering Society's design guidelines and in compliance with International Dark-Sky Association–approved fixtures. All lighting will be designed to have minimum impact on the surrounding environment and will use downcast, cut-off type fixtures that are shielded and direct the light only toward objects requiring illumination. Therefore, lights will be installed at the lowest allowable height and cast low-angle illumination while minimizing incidental light spill onto adjacent properties or open spaces, or backscatter into the nighttime sky. The lowest allowable wattage will be used for all lighted areas, and the amount of nighttime lights needed to light an area will be minimized to the highest degree possible. Light fixtures will have non-glare finishes that will not cause reflective daytime glare. Lighting will be designed for energy efficiency, with daylight sensors or timers with an on/off program. Lights will provide good color rendering with natural light qualities, with the minimum intensity feasible for security, safety, and personnel access. Lighting, including light color rendering and fixture types, will be designed to be aesthetically pleasing.

  LED lighting will avoid the use of blue-rich white light lamps and use a correlated color temperature that is no higher than 3,000 Kelvin, consistent with the International Dark-Sky Associations Fixture Seal of Approval Program (International Dark-Sky Association 2010a, 2010b, 2015). In addition, LED lights will use shielding to ensure that nuisance glare and that light spill does not affect sensitive residential viewers.

  Lights along pathways and bridge safety lighting will use shielding to minimize offsite light spill and glare, and will be screened and directed away from adjacent uses to the highest degree possible. The amount of nighttime lights used along pathways will be minimized to the highest degree possible to ensure that spaces are not unnecessarily over-lit. For example, the amount of light can be reduced by limiting the amount of ornamental light posts to higher use areas and by using bollard lighting on travel way portions of pathways.

  Technologies to reduce light pollution evolve over time; design measures that are currently available may help but may not be the most effective means of controlling light pollution once the project is designed. Therefore, all design measures used to reduce light pollution

will use the technologies available at the time of project design to allow for the highest potential reduction in light pollution.

4.1.3 Impacts on Park Facilities

The following mitigation measures should be implemented to reduce impacts on park and recreational facilities due to construction.

- In the event that any inadvertent damage occurs to the Sacramento Riverwalk Trail, the area affected will be restored to the condition that existed prior to construction activities or better.
- The City of Sacramento will provide advance notification of the Sacramento Riverwalk Trail closure on its websites and trailheads. Notices will include trail closure dates, approximate duration, and description of the detour available during closure.

4.2 Measures to Reduce Growth Inducement Impacts

The project is not anticipated to induce growth. Therefore, no measures to reduce impacts are proposed.

4.3 Measures to Reduce Social Impacts

4.3.1 Community Cohesion Effects

The community cohesion impacts of the project are anticipated to be minor. Therefore, no measures to reduce impacts are proposed.

4.3.2 Access and Circulation Impacts

A TMP is a program of activities for alleviating or minimizing work-related traffic delays by applying traditional traffic handling practices and innovative strategies including public awareness campaigns, motorist information, demand management, incident management, system management, construction methods and staging, and alternate route planning. TMP strategies also strive to reduce overall duration of work activities where appropriate. Typical components of a TMP can include measures such as the implementation of staging, traffic handling, and detour plans; restricting construction work to certain days and/or hours to minimize impacts to traffic and pedestrians; coordination with other construction projects to avoid conflicts; and the use of portable changeable message signs to inform the public of construction activities.

Implementation of the measures in the TMP would reduce the temporary access and circulation impacts of the project caused by potentially lengthy construction delays. In addition to the measures described above, the TMP will include the following measures:

- Any emergency service agency whose ability to respond to incidents will be affected by any lane closure must be notified prior to that closure.
- Work will be coordinated with the local busing system (including school buses and public systems) to minimize impacts on their bus schedules.
- The lead agency will provide information to residents and businesses before and during project work that may represent a negative impact on commerce and travel surrounding the zone of construction.

4.3.3 Emergency Services Impacts

Implementation of the TMP would reduce potential impacts on the response times of emergency service providers (including law enforcement, fire protection, and ambulance service providers) caused by potential construction delays. Therefore, no additional measures to reduce impacts are proposed.

4.3.4 Effects on Utilities, Public Services and Communications Providers

Early notification of utility service and communications providers would help to ensure that patrons are notified prior to any temporary loss of service.

4.3.5 Environmental Justice Effects

No environmental justice effects are anticipated to result from the project. Therefore, no measures to reduce impacts are proposed.

4.4 Measures to Reduce Acquisition/Displacement/Relocation Impacts

As stated in Chapter 3, there would be acquisition required from several parcels in the project area for new right-of-way. No businesses would be displaced as a result of the project. Acquisitions and compensation to residential property owners would occur consistent with the Federal Uniform Relocation Assistance and Real Properties Acquisition Policies Act, as amended.

4.5 Measures to Reduce Economic Impacts

4.5.1.1 Economic Effects on Businesses from Construction Delays and Road Closures

Business notification measures included in the TMP for the project would reduce potential effects on local businesses from construction delays. Therefore, no measures to reduce impacts are proposed.

4.5.1.2 Economic Effects on Businesses from Construction

The construction-related economic effects of the project are anticipated to be beneficial. Therefore, no measures to reduce impacts are proposed.

4.5.1.3 Temporary Effects on Local Tax Revenue

The local tax revenue effects of the proposed project are anticipated to be minor. Therefore, no measures to reduce impacts are proposed.

4.6 Measures to Reduce Cumulative Impacts

Implementation of measures above recommended for the project would reduce the cumulative impacts of the project. No additional impact-reducing measures are proposed.

1. Introduction

1.1 Purpose and Scope

The I Street Bridge Replacement Project consists of the planning, design and construction of a new bridge across the Sacramento River between the City of Sacramento, Sacramento County, California and the City of West Sacramento, Yolo County, California. GEI Consultants (GEI), under subcontract to Mark Thomas and Company has prepared this Preliminary Geotechnical and Foundation Report, in accordance with Caltrans guidelines, to assist in the preliminary design of the I Street Bridge Replacement Project. We prepared this report as outlined in our agreement dated March 19, 2014 between GEI and Mark Thomas and Company. Our authorized scope of services includes the following:

- Reviewing existing subsurface data and foundation plans for bridges and structures in the project vicinity;
- Preparing a vicinity map and exploration location map with pertinent geology, including the approximate location of previous explorations performed by others;
- Evaluating the geologic and seismic setting of the site
- Evaluating the subsurface conditions including estimates of groundwater level and possible seasonal variations in the level;
- Evaluating conceptual foundation types including depths of foundations;
- Evaluating the bridge foundation / levee impacts and potential modifications, as applicable, and;
- Providing recommendations for geotechnical studies for final design.

This report was prepared for the exclusive use of Mark Thomas and Company and their consultants for design of this project. In the event that any changes are made in the character, design or layout of the project, we must be contacted to review the conclusions and recommendations contained in this report to determine whether modifications are necessary.

1.2 Project Location

The project location is shown in Appendix I, Figure 1, the Site and Exploration Location Plan. The new I Street Bridge will cross the Sacramento River between the former railyard in Sacramento and the City of West Sacramento. Figure 1 includes the proposed bridge alignments and the approximate location of available historic explorations.

1.3 Project Description

The cities of Sacramento and West Sacramento have proposed the replacement of the I Street Bridge. The existing I Street Bridge is a steel double-decker swing bridge. The upper deck

is a two lane roadway for vehicular traffic with narrow sidewalks for pedestrians, and the lower deck is for railroad use. The existing bridge will remain in place for railroad purposes. The new moveable bridge will be located north of the existing bridge and will cross approximately from the existing connector in West Sacramento to either Railyards Boulevard or Camille Lane in Sacramento. At the time of this report, (May 2014) the final alignment and type of bridge are still being formulated.

2. Data Review

2.1 Data Collection and Review

GEI reviewed the following existing information and files that was provided in electronic format:

1. Phase 1 Geotechnical Data Report (P1GDR) for the Sacramento River Study Area, prepared by URS, GEI Consultants, and Fugro, November 2008.

2. Supplemental Geotechnical Data Report (SGDR) for the Sacramento River Study Area, prepared by URS, GEI Consultants, and Fugro, September 2011.

3. Final Geotechnical Report for the 5th Street North of UPRR as part of the Railyards Boulevard Improvements Project, prepared by Blackburn Consulting, July 2010.

4. Memorandum of Understanding Respecting the Sacramento River Flood Control Project, USACE, November 6, 1953

5. West End Viaduct As-Built Plans, prepared by State of California, Highway Transportation Agency, dated December 1966.

6. Geotechnical Evaluation Report (GER) Volume 1, Existing Conditions for the West Sacramento Study Area prepared by URS, GEI Consultants, and Fugro, November 2012.

7. Phase 1 Geotechnical Data Report (P1GDR) for the West Sacramento River Study Area, prepared by URS, GEI Consultants, and Fugro, August 2008.

2.2 Explorations and Testing

No project-specific field explorations were performed by GEI in performance of our geotechnical study for the project. Subsurface data from the logs of historic borings provided in the reference documents were used to develop the preliminary stratigraphy and site characterization estimated in this report. The available explorations within approximately 1,000 feet of the planned bridge alignments included 15 exploratory borings and 6 cone penetration tests (CPT). No site specific laboratory strength tests are available within the project vicinity. The logs provided standard penetration test blow counts (SPT) and limited index testing. This information along with the CPT data were used to develop soil strength and consistency

For final design of the project, additional field exploration including CPTs and borings will be necessary to develop final geotechnical engineering properties, and design criteria for bridge foundations, project retaining wall, earthwork, and pavement design. GEI recommends performing additional field work and laboratory testing as described in Section 4.5 – Additional Field Work and Laboratory Testing.

2.3 Mapping

The base topographic map used for the project has been developed from a light detection and ranging (LiDAR) and bathymetry survey developed for ULE. ULE LiDAR data was collected in 2007 along a limited swath along the Sacramento River, typically covering from the levee to the river water surface and approximately 300 feet to the landside of the levee. The ULE survey report indicates the data was collected with vertical accuracy of 4 inches and horizontal accuracy of 6 inches. The ULE bathymetric survey of the Sacramento River was performed between November 2007 and January 2008. The ULE LiDAR data and bathymetric survey were compiled into one GIS format dataset and was provided to GEI by DWR. Landward of the available ULE LiDAR data, additional topographic information is available from DWR's Central Valley Floodplain Evaluation and Delineation (CVFED) LiDAR collected between October 2008 and February 2009. Metadata available with the CVFED LiDAR indicates the data meets the 3.5 feet horizontal accuracy standard at the 95% confidence level and post processed LiDAR elevations have been tested to 4-inch vertical accuracy at 95 percent confidence level. CVFED LiDAR is not displayed in the site plan maps (Plates 1 to 41) but was used to develop the analysis cross sections where they extend beyond the coverage of the ULE LiDAR.

2.4 Existing Structures

The eastern end of the proposed bridge alignments are adjacent to the existing West End Viaduct, and Jibboom Street Viaduct, and near Interstate 5. Previous exploratory boring logs are available for West End Viaduct, but no existing as-built foundation information was available for this review. In addition, no existing as-built foundation information of Interstate 5 was available for this review.

The Jibboom Street viaduct and bridge as-builts are available for this review. The Jibboom Street Bridge spans the American River approximately 3,000 feet north of the planned I Street Replacement Bridge alignments. The Jibboom Street Bridge consists of 5 piers (three piers within the river and one on each abutment). The pile plan shows pile groups with 23 piles spaced at 5.5 feet with the bridge bents. The pile cap is at elevation -10.0 and the bottom of pile at elevation -50.0. The Jibboom Street viaduct as-builts contain limited discernable information, but the details suggest pile spacing of 3 feet within the pile groups supporting the viaduct footings. Viaduct footing pile depths are unknown. The design pile capacity of the Jibboom Street Bridge and Viaduct are unknown.

Other features in vicinity to the planned bridge alignments include two existing 30-inch abandoned waterlines and one active existing 42-inch water line exist running within the east levee embankment. One 12-inch Kinder Morgan line runs perpendicular to the levee embankment on the east embankment.

3. Site Geology and Subsurface Conditions

3.1 Site Geology

Sacramento and the project site are situated within the Great Valley geomorphic province of California. The Great Valley is a gently-sloping to flat alluvial plain east of the Coastal Ranges and west of the Sierra Nevada. It is a northwest trending structural trough that was formed by the westward tilting of the Sierra Nevada block.

The Sacramento Valley in general is underlain by alluvial, lacustrine and marine sedimentary deposits that have accumulated as the structural trough formed and the adjacent mountain ranges were elevated. The thickness of the sediments varies from a thin veneer along the valley margins to thousands of feet at the axis of the trough.

According to the Geologic Map of the Sacramento Quadrangle (Wagner, D.L., et al, 1981) and the Geologic Map of Late Cenozoic Deposits of the Sacramento Valley and Northern Sierran Foothills (Helley, E.J. and Harwood, D.S., 1985, USGS, Map MF-1790), the site is immediately underlain by Holocene (less than 11,000 years old) age alluvial deposits. The natural alluvial deposits in the area typically consist of unconsolidated silt, sand and gravel, which were deposited by the complex Sacramento and American River system. The recent alluvial deposits are horizontally bedded channeled and relatively thin. These recent alluvial deposits are underlain by older (Pleistocene age) alluvium of the Riverbank and/or Turlock Lake Formations estimated to be between 11,000 and 1.8 million years old. The deeper formations consist of semi-consolidated silt, sand and gravel deposited as alluvial fans by the streams and rivers that drained the Sacramento Valley and Sierra Nevada. The general vicinity of the site is reclaimed land that was filled-in in the time frame of 1860's and 1900's. The magnitude of the fill material that was placed at that time is unknown.

The surface distribution of sediment is generally a function of lateral distance from the river channel and topographic elevation; i.e, sediments are relatively coarser proximal to the river, and finer closer to the river in the low lying areas.

3.2 Subsurface Conditions

The existing borings and cone penetration tests (CPT) performed for levee evaluations on the crest and in the vicinity of the West Sacramento levee (the west end of the planned bridge), encountered approximately 15 feet of loose sand with silt (SP-SM) in the embankment. The sand with silt was underlain by an approximately 9 foot layer of clay (CL), followed by an approximately 16 feet thick layer of sandy silt (ML). The sandy silt was underlain by approximately 35 feet of sand with silt (SP-SM). The apparent densities of the sand with silt ranged from medium dense to very dense. The sand with silt was underlain by approximately

25 feet of very dense gravel (GP), followed by a layer of clay (CL). The maximum depth explored was approximately 115 feet.

The existing borings and cone penetration tests on the east end (city of Sacramento) of the planned bridge at the crest of existing levee encountered approximately 6 feet of loose sand with silt (SP-SM). The sand with silt was underlain by approximately 10 feet of loose sand (SP), followed by approximately 7 feet of sandy silt (ML). The sandy silt layer was underlain by approximately 50 feet of sand with silt (SP-SM). The densities of the sand with silt layer varied from loose to medium dense. The sand with silt layer was underlain by an approximately 23 feet thick layer of medium dense to very dense gravel (GP), followed by a layer of clay (CL). The maximum depth explored was approximately 110 feet.

The historic boring logs are provided in Appendix III. The locations of the existing borings and cone penetration tests are shown in Appendix I, Figure 1.

3.2.1 Soil Types

The extent and composition of near surface soil materials at the project site and vicinity have been mapped by the USDA National Resource Conservation Service (NRCS) (USDA, 2013). Maps by the NRCS indicate that the upper 5 feet of the project site is underlain by soils assigned to the Lang sandy sandy loam as well as Sycamore silty loam on the west embankment and Orthents on the east embankment with ground slopes 0 to 2 percent.

3.3 Material Properties

The material properties used in the preliminary studies were determined using empirical correlations to SPT N-values and CPT normalized tip stresses from the information provided in the existing explorations. In selecting strength parameters, distinction was made between freely draining materials and non-freely draining materials. Freely draining materials are defined as coarse-grained materials with little or no plastic fines such that, when sheared, do not generate excess pore water pressure. Table 1 in Appendix II provides details on the stratigraphy, field and laboratory test data, and estimates of material parameters used in the preliminary evaluation of potential bridge foundation types.

3.4 Idealized Soil Profile

Soil conditions on the west embankment are anticipated to consist of a sand with silt embankment overlying a clay (CL) and sandy silt (ML) blanket, and a thick sand with silt aquifer overlying a poorly graded gravel layer and stiff clay layer. Soil conditions on the east embankment are anticipated to consist of a sand with silt embankment underlain by a poorly graded sand and a sandy silt (ML) blanket, and a thick sand with silt aquifer overlying a poorly graded gravel layer and stiff clay layer.

Figures 2 and 3 in Appendix I, show the interpreted stratigraphy and relevant material properties along the Railyard Boulevard bridge alignment, and Figures 4 and 5 show the interpreted stratigraphy and relevant material properties along the Camille Lane bridge alignment.

3.5 Groundwater

Groundwater is expected to vary seasonally. Groundwater was encountered during previous drilling explorations at a depth of approximately 15 to 25 feet below the ground surface (Elevation ranging from approximately 0 to 5.5 feet NAVD88).

Groundwater levels can vary over time in response to environmental/seasonal and land use changes. For this reason, groundwater levels at the time of construction or in the future could differ from those indicated in previous boring logs.

4. Recommendations

4.1 Scour Evaluation

Preliminary evaluation of scour potential was limited to a qualitative analysis of the materials that were encountered in the borings on the east and west bank of the river below the channel elevation. In general, the materials observed below the river bottom consist of sand with silt overlying sand with gravel and gravel. The river bottom material is potentially susceptible to scour. GEI recommends at least one exploration be done in the river channel to confirm the river channel material, and better quantify the potential for scour.

4.2 Corrosion Evaluation

The USDA (NRCS) web soil survey indicates pH values in the range of 5.1 to 8.4 at the site.

Caltrans considers a site to be corrosive to foundation elements if one or more of the following conditions exist (Caltrans, "Corrosion Guideline", Version 1.0, September 2003):

- Chloride concentration is greater than or equal to 500ppm,
- Sulfate concentration is greater than or equal to 2000ppm, or
- pH is 5.5 or less.

Based on the available information from USDA (NRCS), some soils within the project vicinity may be susceptible to corrosion in the top 6 inches. This information is only available for the western bridge abutment. Further site specific investigation and laboratory testing of soil is recommended to provide a more detailed evaluation.

4.3 Seismic Design

4.3.1 Ground Motion Information

Deterministic and probabilistic acceleration response spectra (ARS) were generated using Caltrans ARS Online (Caltrans, 2013). The ARS curves are included in Figure 7. The Caltrans ARS Online website describes how this web-based tool calculates spectra based on the criteria provided in Appendix B of Caltrans Seismic Design Criteria (Caltrans, 2010):

> *The deterministic spectrum is determined as the average of median response spectra calculated using the Campbell-Bozorgnia (2008) and Chiou-Youngs (2008) ground motion prediction equations developed under the "Next Generation Attenuation" project coordinated through the PEER-Lifelines program. These equations are applied to all faults considered to be active in*

the last 750,000 years (late-Quaternary age) that are capable of producing a moment magnitude earthquake of 6.0 or greater. The probabilistic spectrum is obtained from the USGS (2008) National Hazard Map for 5% probability of exceedance in 50 years. Caltrans design spectrum is based on the larger of the deterministic and probabilistic spectral values. Both the deterministic and probabilistic spectra account for soil effects through incorporation of the parameter V_{s30}, the average shear wave velocity in the upper 30 meters of the soil profile.

To develop a preliminary V_{s30}, USGS V_{s30} map server online was used. Additional in-situ testing is recommended to develop a site specific V_{s30} value. The shear wave velocities and site location were input into the Caltrans ARS Online website to arrive at the controlling deterministic scenario (CDS) and the ground motions summarized in the table below. The relevant fault map is shown in Figure 6. The preliminary recommended response spectrum is shown in Figure 7. Based on the results of the Caltrans seismic design procedures using ARS online, a maximum considered (975-year return period) peak ground acceleration (PGA) of 0.262g is estimated for the site.

Fault Parameters						Site Parameters			
CDS	FID	Style	Dip (deg)	MM (max)	RRUP (km)	Vs_{30} (m/s)	PGA (g)	NFF	BAF
Great Valley 03 Mysterious Ridge	82	Rev	20	7.0	50.039	240	0.124	1	1
Great Valley 03a Dunnigan Hills	95	Rev	20	6.4	26.45	240	0.144	1	1
San Andreas 2011 CFM	80	SS	90	8	127.82	240	0.066	1	1

4.3.2 Seismic Hazards

4.3.2.1 Liquefaction

Liquefaction describes the loss of shear strength in saturated soils as a result of pore pressure increasing due to ground shaking. Liquefaction typically occurs in saturated near-surface soil

layers consisting of poorly graded loose sands and gravels, and non-plastic silts (Kramer, 1996).

The historic exploratory borings revealed that the project site is underlain by clean to silty sands in a loose to medium dense condition below the groundwater table. The clean to silty sand layer starts at an approximate elevation of 0 to 10 feet (NAVD88) and ranges from 35 to 45 feet thick. This soil layer was found to be prone to liquefaction. Liquefaction analyses were performed on several historic explorations that include this silty sandy layer. In addition to the analyses performed, liquefaction analyses have been performed within this area in several referenced reports including the Problem Identification Report (PIR) of Sacramento River East Levee Downstream of American River prepared by Kleinfelder (2013), the Final Geotechnical Report for the 5th Street North of UPRR as part of the Railyards Boulevard Improvements Project prepared by Blackburn Consulting (2010), and the Geotechnical Evaluation Report (GER) Volume 1 on Existing Conditions for the West Sacramento Study Area prepared by URS, GEI Consultants, and Fugro (2012).

Liquefaction analyses were performed on borings WM0004_015B, WM0004_031B, WM0004_015C, WM0004_014C, and WM0004_030C on the west embankment and WSESAR_002C on the east embankment. Liquefaction analysis was performed according to the methods recommended in the "Liquefaction Resistance of Soils: Summary Report from 1996 NCEER and 1998 NCEER/NSF Workshops on Evaluation Liquefaction Resistance of Soils," by Youd et al. (2001). A PGA of 0.262 g and magnitude of 7 were used for the analyses, and estimated based on an earthquake having a return period of 975 years. A design water level was assumed to be at an elevation of 20 feet (NAVD 88) to account for seasonal fluctuations in the river. Existing DWR sensor data has indicated groundwater levels up to an elevation 25 feet during the winter months, but ranging between approximately 15 and 25 feet.

In these reports, and our own analyses, normalized CPT tip resistance and blow counts are lower than the liquefaction threshold criteria and, therefore, the site should be considered prone to liquefaction within the silty to clean sand layer. Liquefaction analyses are shown in Appendix IV.

4.4 Preliminary Foundation Considerations

4.4.1 Shallow Foundations

It is our opinion that shallow foundations are not suitable for support of the planned bridge because of the expected high bridge loads and the shallow alluvium that is susceptible to liquefaction. We recommend the planned bridge be supported on deep foundations extending into more competent soils that underlie the site. Deep foundations will allow bridge loads to be transferred to more suitable soils, and minimize settlement of future bridge.

4.4.2 Driven Piles

Driven piles are considered feasible for the support of the bridge structure. Driven piles would consist of precast concrete or steel piles, extending into the dense gravel layer that underlies the site. Driven piles extending into the dense gravel would generate large tip resistance. According to preliminary analysis, a single 16-inch square driven concrete pile, 40 feet in length, is expected to have an ultimate axial pile capacity of approximately 450 kips if embedded 10 feet into the gravel layer (approximate elevation of -48.0 feet NAVD88) within the channel and 580 kips if embedded at the east or west abutment areas.

The bridge abutments and bents would be supported by a group of piles. In general, the axial capacity of pile groups would not be reduced if the piles are spaced a minimum of 3 pile diameters apart, center to center spacing. Pile capacity was determined according to Caltrans Bridge Design Specifications (2003) and NAVFAC Foundation and Earth Structures (1986). Site-specific explorations within the channel will provide a more accurate analysis of pile capacity. Lateral capacity of the driven piles and pile groups will be evaluated during final design. In this evaluation, liquefaction will need to be further analyzed due to the potential adverse impacts to pile performance.

4.4.3 Drilled Piles

Cast-In-Drilled-Hole (CIDH) piles are considered potentially feasible for the support of the bridge structure. Single CIDH foundations would likely have larger capacities that a single driven pile. However, several challenges exist including drilling in and extending CIDH foundation elements through expected saturated sands. The coarse grained alluvial soils would likely cave during drilling without slurry or temporary casing being utilized for ground support.

Further study of the CIDH foundation option with the use of permanent casing may be warranted if large foundation loads preclude the use of driven pile groups.

4.5 Levee Impacts

According to the USACE *Clarification Guidance on the Policy and Procedural Guidance for Approval of Modifications and Alterations of Corp of Engineers Projects*, bridge construction should consider the impact of bridge construction on the general performance of the levee with consideration of the full range of loading conditions. Considerations during bridge design and construction should include, but not be limited to: backfill material and compaction requirements, bridge abutments effect on scour and erosion along the embankment, underseepage, through seepage, and slope stability. Further evaluation of levee performance will be performed as the bridge design is finalized.

4.6 Additional Field Work and Laboratory Testing

GEI recommends additional field exploration and laboratory testing be performed as the planning and design of the I Street Bridge Replacement Project progresses. At least one exploration is recommended at each bent and abutment location, depending on the size of the pile groups for the abutments and bents. This would include explorations within the Sacramento River channel at planned bent locations. The explorations should include both CPT explorations and rotary wash borings to obtain SPT samples and blow counts in the granular material and high quality undisturbed samples in the fine grained soils.

GEI also recommends that the CPTs include seismic testing to develop a refined site-specific shear wave velocity of design (V_{s30}). The CPT's should be performed in advance of the borings to provide information on the stratigraphy and soil parameters to better plan the boring locations and sampling intervals. The borings will likely be performed with rotary drilling methods to allow for the collection of high quality samples. Laboratory testing should be performed on undisturbed samples retrieved from the borings. Testing should include, at a minimum, index testing, sieve analyses, soil corrosivity, consolidation testing, and triaxial compression testing.

5. Closure

This Preliminary Geotechnical and Foundation Report was prepared for Mark Thomas and Company for use in planning and preliminary design of the proposed I Street Bridge Replacement Project.

GEI prepared the conclusions, recommendations, and professional opinions of this report in accordance with the generally accepted geotechnical principles and practices at this time and location. This report and the drawings contained in this report are intended for preliminary design-input purposes; they are not intended to act as final design input, construction drawings, or specifications.

The scope and services did not include any environmental assessments for the presence or absence of hazardous or toxic materials in the soil, surface water, groundwater, or atmosphere.

Soil and rock deposits can vary in type, strength, and other geotechnical properties between points of observations and explorations. This is a preliminary report which utilizes existing explorations that have been projected to the project location. The recommendations presented within this report are based on these projected explorations, and are subject to confirmation based on further investigation and conditions revealed by construction.

CLASSIFICATION OF MATERIAL BASED ON STANDARD GRADE SIZE LIMITS

Particles behind the sieve the diameter of which is specified as inches or millimeters.
Separation of Class Names.
Words in the term "gravelly" may be substituted for the word "and" in the terms "coarse sand and fine gravel" and "fine gravel and coarse sand".
Terms "coarse," "medium" and "fine" may be used to modify "sand" and "gravel".
Refer to the Unified Soil Classification System for Silt and Gravel.
Refer to Grade Size Limits.

NOTE: Classification of earth material as shown on this sheet is based upon field inspection and is not to be construed to imply mechanical analysis.

Gravel — Silty Clay or Clayey Silt
Sand — Organic Matter
Silt — Fill Material
Clay — Igneous Rock
Sandy Clay or Clayey Sand — Sedimentary Rock
Silty Sand or Silty Gravel — Metamorphic Rock

CLASSIFICATION OF MATERIAL BASED ON STANDARD GRADE SIZE LIMITS

Diagram showing the sizes (in millimeters and inches) and corresponding sieve numbers used to designate the limits of boulders, cobbles, gravel, coarse sand, medium sand, fine sand, and silt or clay. Particles are designated as coarse, medium or fine within the limits of each of the above terms except silt or clay. Particles smaller than the standard sieve size are designated as silt or clay.

NOTE: Classification of earth material as shown on this sheet is based upon field inspection and is not to be construed to imply mechanical analysis.

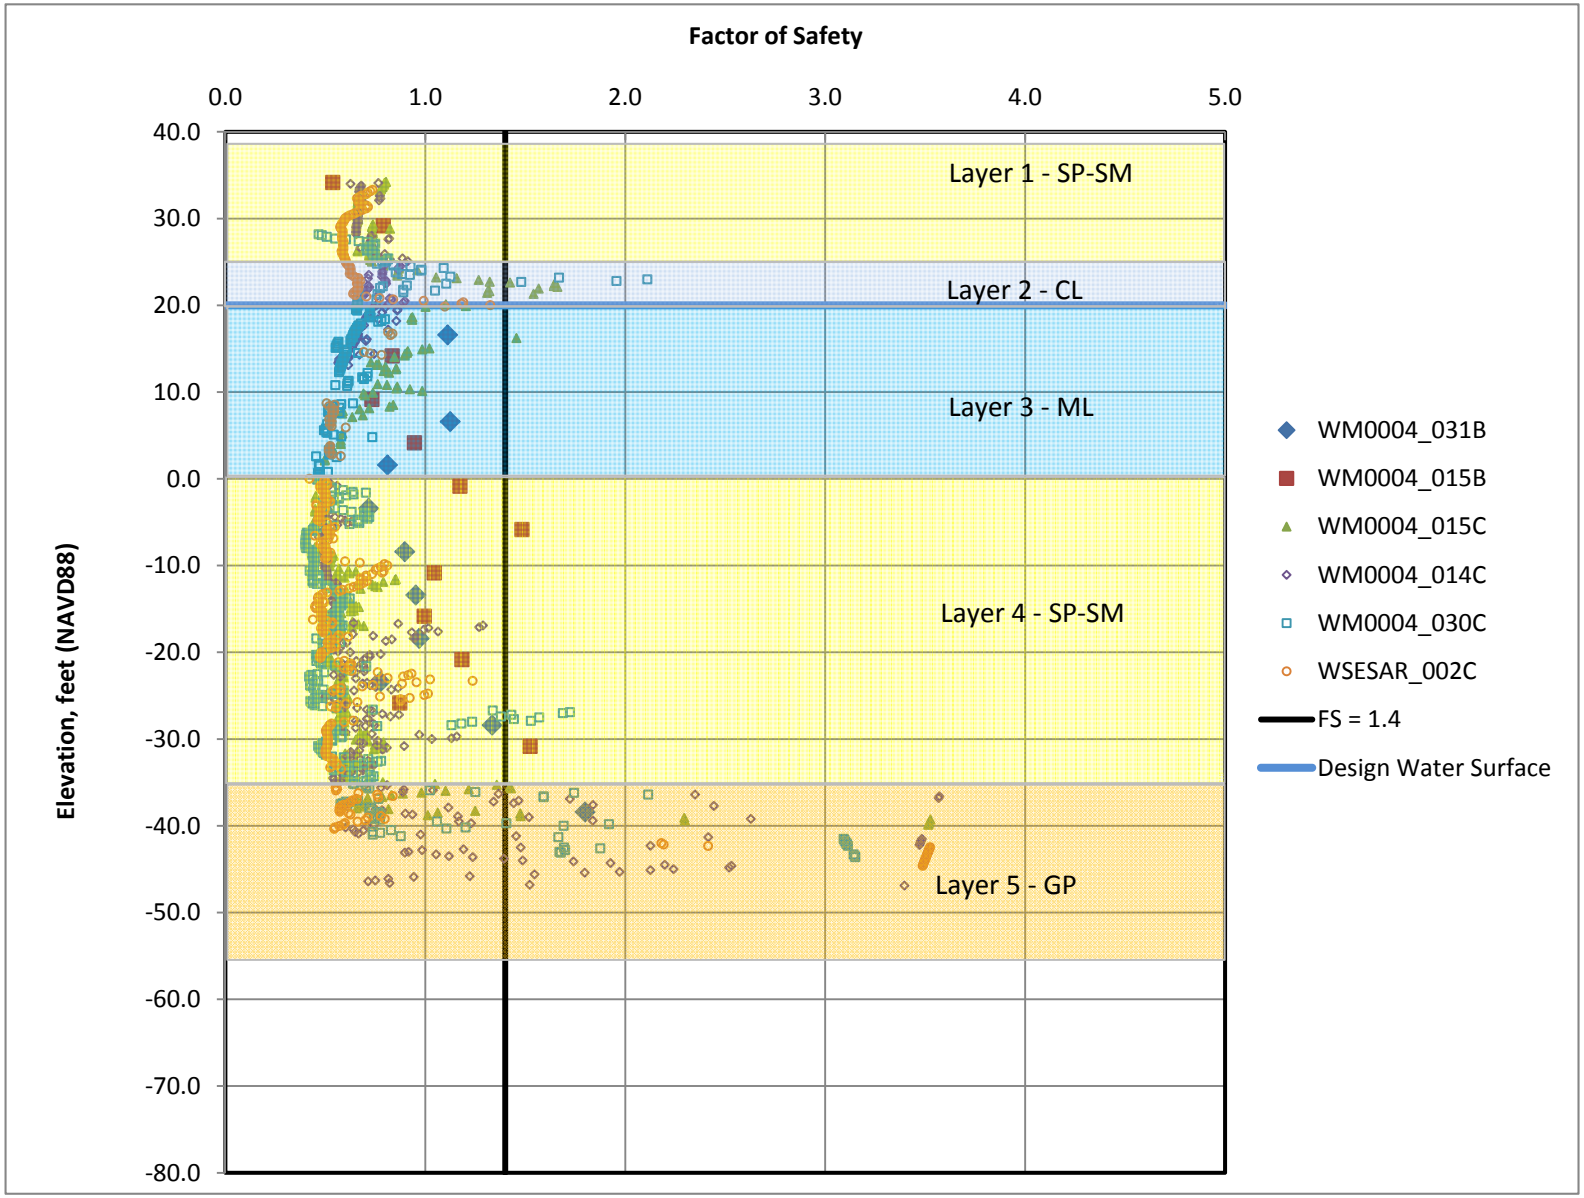
Appendix IV – Liquefaction Analysis

Summary of Liquefaction Susceptibility



Project: I Street Bridge Replacement
Client: Mark Thomas and Company
Subject: EQ Analysis - I Street Bridge

Factors of Safety against Liquefaction
WM0004_002C - I Street Bridge, Sacramento

Purpose: Evaluate susceptibility of sand-like soils to liquefaction.

Method: Use the "simplified procedure" practice for evaluating liquefaction of resistance of soils based on CPT results. The equations are based on the technical update presented in Reference 1 and are listed at the end of the spreadsheet.

References:
1) Youd, T. L. et al. (2001). "Liquefaction Resistance of Soils: Summary Report from the 1996 NCEER and 1998 NCEER/NSF Workshops on Evaluation of Liquefaction Resistance of Soils". J. Geotech. and Geoenv. Engrg., ASCE, 127(4):297-313.

Assumptions:

Unit Wt. of Sand, Silt & Gravel above GWT, γ [pcf]	130.0	Assumed value based on coarser-grained units close to the ground surface
Unit Wt. of Sand, Silt & Gravel below GWT, γ [pcf]	120.0	Assumed value based on finer-grained units further from the ground surface
Earthquake magnitude	7	Magnitude is assumed based off previous WSAFCA Study
Depth to Groundwater at Time of Drilling (ft)	14.6	
Depth to Groundwater for Design (ft)	18.4	
Ground Surface Elevation	38.40	Ground Surface Elevation Listed on CPT log
Earthquake PGA (g)	0.262	

Youd et al 2001 Eqn. No.	Equation
12, 13	$q_{c1N} = C_Q(q_c/p_{atm})$ where $C_Q = (p_{atm}/\sigma'_{vo})^n$
18, 19	$q_{c1Ncs} = K_c q_{c1N}$ where $K_c = -0.403I_c^4 + 5.581I_c^3 - 21.63I_c^2 + 33.75I_c - 17.88$ for $I_c > 1.64$; $K_c = 1.0$ for $I_c <= 1.64$
11a,b	$CRR_{7.5} =$ $0.833(q_{c1Ncs}/1000) + 0.05$ for $q_{c1Ncs} < 50$; $93(q_{c1Ncs}/1000)^3 + 0.08$ for $50 \le q_{c1Ncs} < 160$; 0.60 for $q_{c1Ncs} \ge 160$
1	$CSR = \tau_{av} / \sigma'_{vo,b} = 0.65\,(a_{max}/g)(\sigma_{o,t,b}/\sigma'_{vo,b})r_d$
24	$MSF = 10^{2.24} / Mw^{2.56}$
31	$K_\sigma = [(\sigma'_v)_b / P_a]^{(f-1)}$ where f = 0.75 for an assumed relative density of 50%
30	$FS = (CRR_{7.5} / CSR) * MSF * K_\sigma$

Notes:
1) Yellow cells = cell which is input by the user (cells not highlighted are computed by Excel).
2) Qt1 is the normalized cone tip resistance for an exponent n equal to 1.0. This is also equal to the conventional normalized tip resistance, Q, as has been previously used (e.g. Robertson 1990).
3) Ic (n=1) indicates that the soil behavior type index Ic is calculated by assuming n is equal to 1.0. Ic is defined in equation 14 of Youd et al. 2001.
4) $(\sigma'_{vo})_a$ is the vertical effective stress computed using the depth to water at the time of drilling.
5) $(\sigma'_v)_b$ is the vertical effective sress computed using the depth to water during the earthquake.
6) If Ic (n=1) is less than 2.6 and the updated Ic (column Q) is greater than 2.6, set n to 0.7 and recalculate Qtn and Ic
7)
8) Ic < 2.6 is the nominal range of liquefiable soils, per the Robertson and Wride (1998) method.
9) Data points with Ic > 2.6 are included in the triggering evaluations if the exponent n is manually set to 0.7 to be consistent with SPT or laboratory classification of soils.

Boring No.	Depth [ft]	Elev. Project: I Street Bridge Replacement
Client: Mark Thomas and Company
Subject: EQ Analysis - I Street Bridge

Factors of Safety against Liquefaction
WM0004_0014C - I Street Bridge, Sacramento

Purpose: Evaluate susceptibility of sand-like soils to liquefaction.

Method: Use the "simplified procedure" practice for evaluating liquefaction of resistance of soils based on CPT results. The equations are based on the technical update presented in Reference 1 and are listed at the end of the spreadsheet.

References:
1) Youd, T. L. et al. (2001). "Liquefaction Resistance of Soils: Summary Report from the 1996 NCEER and 1998 NCEER/NSF Workshops on Evaluation of Liquefaction Resistance of Soils". J. Geotech. and Geoenv. Engrg., ASCE, 127(4):297-313.

Assumptions:

Unit Wt. of Sand, Silt & Gravel above GWT, γ [pcf]	130.0	Assumed value based on coarser-grained units close to the ground surface
Unit Wt. of Sand, Silt & Gravel below GWT, γ [pcf]	120.0	Assumed value based on finer-grained units further from the ground surface
Earthquake magnitude	7	Magnitude is assumed based off previous WSAFCA Study
Depth to Groundwater at Time of Drilling (ft)	30.8	
Depth to Groundwater for Design (ft)	19.2	
Ground Surface Elevation	39.20	Ground Surface Elevation Listed on CPT log
Earthquake PGA (g)	0.262	

Youd et al 2001 Eqn. No.	Equation
12, 13	$q_{c1N} = C_Q(q_c/p_{atm})$ where $C_Q = (p_{atm}/\sigma'_{vo})^n$
18, 19	$q_{c1Ncs} = K_c q_{c1N}$ where $K_c = -0.403I_c^4 + 5.581I_c^3 - 21.63I_c^2 + 33.75I_c - 17.88$ for $I_c > 1.64$; $K_c = 1.0$ for $I_c <= 1.64$
11a,b	$CRR_{7.5} =$ $0.833(q_{c1Ncs}/1000) + 0.05$ for $q_{c1Ncs} < 50$; $93(q_{c1Ncs}/1000)^3 + 0.08$ for $50 \le q_{c1Ncs} < 160$; 0.60 for $q_{c1Ncs} \ge 160$
1	$CSR = \tau_{av} / \sigma'_{vo,b} = 0.65\,(a_{max}/g)(\sigma_{o,t,b}/\sigma'_{vo,b})r_d$
24	$MSF = 10^{2.24} / Mw^{2.56}$
31	$K_\sigma = [(\sigma'_v)_b / P_a]^{(f-1)}$ where f = 0.75 for an assumed relative density of 50%
30	$FS = (CRR_{7.5} / CSR) * MSF * K_\sigma$

Notes:
1) Highlighted = cell which is input by the user (cells not highlighted are computed by Excel).
2) Qt1 is the normalized cone tip resistance for an exponent n equal to 1.0. This is also equal to the conventional normalized tip resistance, Q, as has been previously used (e.g. Robertson 1990).
3) Ic (n=1) indicates that the soil behavior type index Ic is calculated by assuming n is equal to 1.0. Ic is defined in equation 14 of Youd et al. 2001.
4) $(\sigma'_{vo})_a$ is the vertical effective stress computed using the depth to water at the time of drilling.
5) $(\sigma'_v)_b$ is the vertical effective sress computed using the depth to water during the earthquake.
6) If Ic (n=1) is less than 2.6 and the updated Ic (column Q) is greater than 2.6, set n to 0.7 and recalculate Qtn and Ic
7)
8) Ic < 2.6 is the nominal range of liquefiable soils, per the Robertson and Wride (1998) method.
9) Data points with Ic > 2.6 are included in the triggering evaluations if the exponent n is manually set to 0.7 to be consistent with SPT or laboratory classification of soils.

I Street Bridge Liquefaction Evaluation
Geotechnical Evaluation
Liquefaction Triggering Evaluation

Purpose: Evaluate susceptibility of sand-like soils to liquefaction.

Boring: **WM0004_015B** **West Embankment**

Method:
1) If no Atterberg limits are available for soil samples, the soil will be assumed to behave as sand-like. Note that silty clays with no Atterberg limits are included as sand-like.
2) For all soils assumed to behave as sand-like, compute $(N_1)_{60}$.
3) For potentially contractive sand-like soils [$(N_1)_{,60} < 30$], compute the factor of safety against pore pressure increase (Youd et al 2001).
4) If potentially contractive sand-like soils have a factor of safety ≤ 1.4, assume the soil is susceptible to liquefaction.

References:
1) Youd, T. L. et al. (2001). "Liquefaction Resistance of Soils: Summary Report from the 1996 NCEER and 1998 NCEER/NSF Workshops on Evaluation of Liquefaction Resistance of Soils". J. Geotech. And Geoenv. Engrg., ASCE, 127(4):297-313.

Assumed:

Ground Surface Elevation at Time of Drilling (ft)	39.2	Ground surface elevation taken from boring log
Ground Surface Elevation at Time for Design (ft)	39.2	Assume same ground surface for evaluation
Unit Wt. of soil 1 (pcf)	120	Assumed unit weight above the groundwater table
Unit Wt. of soil 2 (pcf)	130	Assumed unit weight below the groundwater table
Earthquake Magnitude (M_w)	7.0	Magnitude is assumed based off previous WSAFCA Study
Earthquake PGA (g)	0.262	Assumed based off previous WSAFCA Study
Elevation of Groundwater at Time of Drilling (ft)	9.1	Value reported in log of Boring 123 in FSAR Appendix I
Elevation of Groundwater at Time for Design (ft)	20.0	Assumed to be at ground surface for design
Depth to Groundwater at Time of Drilling (ft)	30.1	Calculated from Groundwater Table Elevation at Drilling (above cell)
Depth to Groundwater for Design (ft)	19.2	Calculated from Groundwater Table Elevation at Design (above cell)
Length of Drilling Rod above the Ground Surface (ft)	5.0	Assumed

Corrections for hammer energy, borehole diameter, rod length, and sampling method (Ref. 1, Table 2):

Factor	Term	Equipment Variable	Correction
Energy Ratio	C_E	Energy ratio = 83.9%	1.4
Borehole Diameter	C_B	Diameter < 115 mm (assumed)	1.05
Sampling Method	C_S	Sampler without Liner (assumed)	1.0
Rod Length	C_R	0 ≤ d ≤ 3 m	0.75
		3 < d ≤ 4 m	0.80
		4 < d ≤ 6 m	0.85
		6 < d ≤ 10 m	0.95
		d > 10 m	1.00

Youd et al 2001 Eqn. No.	Equation
8, 10	$(N_1)_{60} = Nm * C_N * C_E * C_B * C_S * C_R$ where $C_N = 2.2/[1.2 + (\sigma'_{v0,a}/P_a)]$ and P_a = 2116 psf (= 101 kPa)
5	$(N_1)_{60cs} = \alpha + \beta(N_1)_{60}$ where: α=0 for FC≤5%, $\alpha=\exp[1.76 - 190/(FC)^2]$ for 5%<FC<35%, α=5 for FC≥35%; β=1 for FC≤5%, $\beta=[0.99 + (FC)^{1.5}/1000]$ for 5%<FC<35%, β=1.2 for FC≥35%
4	$CRR_{7.5} = 1/[34-(N_1)_{60cs}] + (N_1)_{60cs} / 135 + 50 / [10(N_1)_{60cs} + 45]^2 - 1/200$ for $(N_1)_{60cs} < 30$
1	$CSR = \tau_{av} / \sigma'_{v0,b} = 0.65 (a_{max}/g)(\sigma_{v0,b}/\sigma'_{v0,b})r_d$
2	$r_d = (1.0 - 0.00765*z)$ for z ≤ 9.15m and $r_d = (1.174 - 0.0267*z)$ for 9.15m < z ≤ 23m, where z is the depth below the design ground surface
24	$MSF = 10^{2.24} / Mw^{2.56}$
31	$K_\sigma = [\sigma'_{v0,b} / P_a]^{(f-1)}$ where f = 0.75 for an assumed relative density of 50%
30	$FS_L = (CRR_{7.5} / CSR) * MSF * K_\sigma$

Calculated By: _____
Date: _____
Checked By: _____
Date: _____

Notes:

1) = cell which is input by the user (cells not highlighted are computed by Excel).
2) N_m = Uncorrected blowcounts measured in the field.
3) FC = measured fines content (% passing the No. 200 sieve) and PI = measured plasticity index.
4) $\sigma'_{v0,a}$ is the vertical effective stress computed using the depth to water at the time of drilling.
5) $\sigma_{v0,b}$ is the total vertical stress for design.
6) $\sigma'_{v0,b}$ is the vertical effective stress computed using the depth to water for design.
7) In the absense of laboratory fines contents, an estimate of the fines content is made based on the field soil description: SP-SM = 5% Fines, Silty or Clayey = 12% Fines, Clays or Silts = 50% Fines.
8) Samples with $(N_1)_{60cs}$ > 30 are considered non-liquefiable and are screened out of the analysis, per Youd et al. (2001). Samples may also be screened out of the analysis for other reasons, which shall be described in the Notes column.
9) The depth reduction factor r_d, as defined in Youd et al. (2001), is only provided for soils shallower than 23 meters. r_d values at samples deeper than 23 meters at design are conservatively assigned an r_d value corresponding to a depth of 23 meters.

Project: I Street Bridge Replacement
Client: Mark Thomas and Company
Subject: EQ Analysis - I Street Bridge

Factors of Safety against Liquefaction
WM0004_0015C - I Street Bridge, Sacramento

Purpose: Evaluate susceptibility of sand-like soils to liquefaction.

Method: Use the "simplified procedure" practice for evaluating liquefaction of resistance of soils based on CPT results. The equations are based on the technical update presented in Reference 1 and are listed at the end of the spreadsheet.

References:
1) Youd, T. L. et al. (2001). "Liquefaction Resistance of Soils: Summary Report from the 1996 NCEER and 1998 NCEER/NSF Workshops on Evaluation of Liquefaction Resistance of Soils". J. Geotech. and Geoenv. Engrg., ASCE, 127(4):297-313.

Assumptions:

Unit Wt. of Sand, Silt & Gravel above GWT, γ [pcf]	130.0	Assumed value based on coarser-grained units close to the ground surface
Unit Wt. of Sand, Silt & Gravel below GWT, γ [pcf]	120.0	Assumed value based on finer-grained units further from the ground surface
Earthquake magnitude	7	Magnitude is assumed based off previous WSAFCA Study
Depth to Groundwater at Time of Drilling (ft)	30.2	
Depth to Groundwater for Design (ft)	19.32	
Ground Surface Elevation	39.32	Ground Surface Elevation Listed on CPT log
Earthquake PGA (g)	0.262	

Youd et al 2001 Eqn. No.	Equation
12, 13	$q_{c1N} = C_Q(q_c/p_{atm})$ where $C_Q = (p_{atm}/\sigma'_{vo})^n$
18, 19	$q_{c1Ncs} = K_c q_{c1N}$ where $K_c = -0.403I_c^4 + 5.581I_c^3 - 21.63I_c^2 + 33.75I_c - 17.88$ for $I_c > 1.64$; $K_c = 1.0$ for $I_c <= 1.64$
11a,b	$CRR_{7.5} = 0.833(q_{c1Ncs}/1000) + 0.05$ for $q_{c1Ncs} < 50$; $93(q_{c1Ncs}/1000)^3 + 0.08$ for $50 \le q_{c1Ncs} < 160$; 0.60 for $q_{c1Ncs} \ge 160$
1	$CSR = \tau_{av} / \sigma'_{vo,b} = 0.65\,(a_{max}/g)(\sigma_{o,t,b}/\sigma'_{vo,b})r_d$
24	$MSF = 10^{2.24} / Mw^{2.56}$
31	$K_\sigma = [(\sigma'_{vo})_b / P_a]^{(f-1)}$ where f = 0.75 for an assumed relative density of 50%
30	$FS = (CRR_{7.5} / CSR) * MSF * K_\sigma$

Notes:
1) = cell which is input by the user (cells not highlighted are computed by Excel).
2) Qt1 is the normalized cone tip resistance for an exponent n equal to 1.0. This is also equal to the conventional normalized tip resistance, Q, as has been previously used (e.g. Robertson 1990).
3) Ic (n=1) indicates that the soil behavior type index Ic is calculated by assuming n is equal to 1.0. Ic is defined in equation 14 of Youd et al. 2001.
4) $(\sigma'_{vo})_a$ is the vertical effective stress computed using the depth to water at the time of drilling.
5) $(\sigma'_{vo})_b$ is the vertical effective sress computed using the depth to water during the earthquake.
6) If Ic (n=1) is less than 2.6 and the updated Ic (column Q) is greater than 2.6, set n to 0.7 and recalculate Qtn and Ic
7)
8) Ic < 2.6 is the nominal range of liquefiable soils, per the Robertson and Wride (1998) method.
9) Data points with Ic > 2.6 are included in the triggering evaluations if the exponent n is manually set to 0.7 to be consistent with SPT or laboratory classification of soils.

Project: I Street Bridge Replacement
Client: Mark Thomas and Company
Subject: EQ Analysis - I Street Bridge

Factors of Safety against Liquefaction
WM0004_0030C - I Street Bridge, Sacramento

Purpose: Evaluate susceptibility of sand-like soils to liquefaction.

Method: Use the "simplified procedure" practice for evaluating liquefaction of resistance of soils based on CPT results. The equations are based on the technical update presented in Reference 1 and are listed at the end of the spreadsheet.

References:
1) Youd, T. L. et al. (2001). "Liquefaction Resistance of Soils: Summary Report from the 1996 NCEER and 1998 NCEER/NSF Workshops on Evaluation of Liquefaction Resistance of Soils". J. Geotech. and Geoenv. Engrg., ASCE, 127(4):297-313.

Assumptions:

Unit Wt. of Sand, Silt & Gravel above GWT, γ [pcf]	130.0	Assumed value based on coarser-grained units close to the ground surface
Unit Wt. of Sand, Silt & Gravel below GWT, γ [pcf]	120.0	Assumed value based on finer-grained units further from the ground surface
Earthquake magnitude	7	Magnitude is assumed based off previous WSAFCA Study
Depth to Groundwater at Time of Drilling (ft)	14.6	
Depth to Groundwater for Design (ft)	8.4	
Ground Surface Elevation	28.40	Ground Surface Elevation Listed on CPT log
Earthquake PGA (g)	0.262	

Youd et al 2001 Eqn. No.	Equation
12, 13	$q_{c1N} = C_Q(q_c/p_{atm})$ where $C_Q = (p_{atm}/\sigma'_{vo})^n$
18, 19	$q_{c1Ncs} = K_c q_{c1N}$ where $K_c = -0.403I_c^4 + 5.581I_c^3 - 21.63I_c^2 + 33.75I_c - 17.88$ for $I_c > 1.64$; $K_c = 1.0$ for $I_c <= 1.64$
11a,b	$CRR_{7.5} =$ $0.833(q_{c1Ncs}/1000) + 0.05$ for $q_{c1Ncs} < 50$; $93(q_{c1Ncs}/1000)^3 + 0.08$ for $50 \le q_{c1Ncs} < 160$; 0.60 for $q_{c1Ncs} \ge 160$
1	$CSR = \tau_{av} / \sigma'_{vo,b} = 0.65\,(a_{max}/g)(\sigma_{o,t,b}/\sigma'_{vo,b})r_d$
24	$MSF = 10^{2.24} / Mw^{2.56}$
31	$K_\sigma = [(\sigma'_v)_b / P_a]^{(f-1)}$ where f = 0.75 for an assumed relative density of 50%
30	$FS = (CRR_{7.5} / CSR) * MSF * K_\sigma$

Notes:
1) Highlighted = cell which is input by the user (cells not highlighted are computed by Excel).
2) Qt1 is the normalized cone tip resistance for an exponent n equal to 1.0. This is also equal to the conventional normalized tip resistance, Q, as has been previously used (e.g. Robertson 1990).
3) Ic (n=1) indicates that the soil behavior type index Ic is calculated by assuming n is equal to 1.0. Ic is defined in equation 14 of Youd et al. 2001.
4) $(\sigma'_{vo})_a$ is the vertical effective stress computed using the depth to water at the time of drilling.
5) $(\sigma'_v)_b$ is the vertical effective sress computed using the depth to water during the earthquake.
6) If Ic (n=1) is less than 2.6 and the updated Ic (column Q) is greater than 2.6, set n to 0.7 and recalculate Qtn and Ic
7)
8) Ic < 2.6 is the nominal range of liquefiable soils, per the Robertson and Wride (1998) method.
9) Data points with Ic > 2.6 are included in the triggering evaluations if the exponent n is manually set to 0.7 to be consistent with SPT or laboratory classification of soils.

I Street Bridge Liquefaction Evaluation
Geotechnical Evaluation
Liquefaction Triggering Evaluation

Purpose: Evaluate susceptibility of sand-like soils to liquefaction.

Boring: **WM0004_031B** **West Embankment**

Method:
1) If no Atterberg limits are available for soil samples, the soil will be assumed to behave as sand-like. Note that silty clays with no Atterberg limits are included as sand-like.
2) For all soils assumed to behave as sand-like, compute $(N_1)_{60}$.
3) For potentially contractive sand-like soils [$(N_1)_{,60} < 30$], compute the factor of safety against pore pressure increase (Youd et al 2001).
4) If potentially contractive sand-like soils have a factor of safety ≤ 1.4, assume the soil is susceptible to liquefaction.

References:
1) Youd, T. L. et al. (2001). "Liquefaction Resistance of Soils: Summary Report from the 1996 NCEER and 1998 NCEER/NSF Workshops on Evaluation of Liquefaction Resistance of Soils". J. Geotech. And Geoenv. Engrg., ASCE, 127(4):297-313.

Assumed:

Ground Surface Elevation at Time of Drilling (ft)	26.6	Ground surface elevation taken from boring log
Ground Surface Elevation at Time for Design (ft)	26.6	Assume same ground surface for evaluation
Unit Wt. of soil 1 (pcf)	120	Assumed unit weight above the groundwater table
Unit Wt. of soil 2 (pcf)	130	Assumed unit weight below the groundwater table
Earthquake Magnitude (M_w)	7.0	Magnitude is assumed based off previous WSAFCA Study
Earthquake PGA (g)	0.262	Assumed based off previous WSAFCA Study
Elevation of Groundwater at Time of Drilling (ft)	7.9	Value reported in log of Boring 123 in FSAR Appendix I
Elevation of Groundwater at Time for Design (ft)	20.0	Assumed to be at ground surface for design
Depth to Groundwater at Time of Drilling (ft)	18.7	Calculated from Groundwater Table Elevation at Drilling (above cell)
Depth to Groundwater for Design (ft)	6.6	Calculated from Groundwater Table Elevation at Design (above cell)
Length of Drilling Rod above the Ground Surface (ft)	5.0	Assumed

Corrections for hammer energy, borehole diameter, rod length, and sampling method (Ref. 1, Table 2):

Factor	Term	Equipment Variable	Correction
Energy Ratio	C_E	Energy ratio = 83.9%	1.4
Borehole Diameter	C_B	Diameter < 115 mm (assumed)	1.05
Sampling Method	C_S	Sampler without Liner (assumed)	1.0
Rod Length	C_R	0 ≤ d ≤ 3 m	0.75
		3 < d ≤ 4 m	0.80
		4 < d ≤ 6 m	0.85
		6 < d ≤ 10 m	0.95
		d > 10 m	1.00

Youd et al 2001 Eqn. No.	Equation
8, 10	$(N_1)_{60} = Nm * C_N * C_E * C_B * C_S * C_R$ where $C_N = 2.2/[1.2 + (\sigma'_{v0,a}/P_a)]$ and P_a = 2116 psf (= 101 kPa)
5	$(N_1)_{60cs} = \alpha + \beta(N_1)_{60}$ where: α=0 for FC≤5%, α=exp[1.76 - 190/(FC)^2] for 5%<FC<35%, α=5 for FC≥35%; β=1 for FC≤5%, β=[0.99 + (FC)$^{1.5}$/1000] for 5%<FC<35%, β=1.2 for FC≥35%
4	$CRR_{7.5} = 1/[34-(N_1)_{60cs}] + (N_1)_{60cs} / 135 + 50 / [10(N_1)_{60cs} + 45]^2 - 1/200$ for $(N_1)_{60cs} < 30$
1	$CSR = \tau_{av} / \sigma'_{v0,b} = 0.65 (a_{max}/g)(\sigma_{v0,b}/\sigma'_{v0,b})r_d$
2	$r_d = (1.0 - 0.00765*z)$ for z ≤ 9.15m and $r_d = (1.174 - 0.0267*z)$ for 9.15m < z ≤ 23m, where z is the depth below the design ground surface
24	$MSF = 10^{2.24} / Mw^{2.56}$
31	$K_\sigma = [\sigma'_{v0,b} / P_a]^{(f-1)}$ where f = 0.75 for an assumed relative density of 50%
30	$FS_L = (CRR_{7.5} / CSR) * MSF * K_\sigma$

Notes:

1) = cell which is input by the user (cells not highlighted are computed by Excel).
2) N_m = Uncorrected blowcounts measured in the field.
3) FC = measured fines content (% passing the No. 200 sieve) and PI = measured plasticity index.
4) $\sigma'_{v0,a}$ is the vertical effective stress computed using the depth to water at the time of drilling.
5) $\sigma_{v0,b}$ is the total vertical stress for design.
6) $\sigma'_{v0,b}$ is the vertical effective stress computed using the depth to water for design.
7) In the absense of laboratory fines contents, an estimate of the fines content is made based on the field soil description: SP-SM = 5% Fines, Silty or Clayey = 12% Fines, Clays or Silts = 50% Fines.
8) Samples with $(N_1)_{60cs}$ > 30 are considered non-liquefiable and are screened out of the analysis, per Youd et al. (2001). Samples may also be screened out of the analysis for other reasons, which shall be described in the Notes column.
9) The depth reduction factor r_d, as defined in Youd et al. (2001), is only provided for soils shallower than 23 meters. r_d values at samples deeper than 23 meters at design are conservatively assigned an r_d value corresponding to a depth of 23 meters.

TECHNICAL MEMORANDUM

TO: Mark Thomas & Co., c/o Zach Sivilgia, P.E.

PREPARED BY: Michael Archer, P.E.

REVIEWED BY: Don Trieu, P.E.

SUBJECT: Preliminary Hydraulic Impact Analysis for the I Street Bridge Replacement Project

DATE: April 29, 2015

DRAFT

PURPOSE

The purpose of this memorandum is to evaluate the potential impacts of the proposed I Street Bridge Replacement Project on flood stages. The impacts were evaluated for the following flood events:

- 1-in-50 annual exceedance probability (AEP), also known as the 50-year flood or 2% annual chance flood
- 1-in-100 AEP (100-year or 1% annual chance flood)
- 1-in-200 AEP (200-year or 0.5% annual chance flood)

PROJECT DESCRIPTION

The proposed project consists of the construction of a new bridge across the Sacramento River approximately 1,100 feet upstream of the existing I Street bridge (Figure 1) and about 3,000 feet downstream of the American River. The existing bridge will remain in place. A design drawing of the proposed bridge is shown in Figure 2. The bridge is a lift span supported by two towers; the preliminary design has two options for the piers (piers 3 and 4 in Figure 2): 1) a single solid pier at each tower, or 2) four 12-foot-diameter piers at each tower. The design also includes a fender system effectively surrounding the tower piers. A single pier is located on both sides of the lift span between the river bank and the tower (piers 2 and 5 in Figure 2).

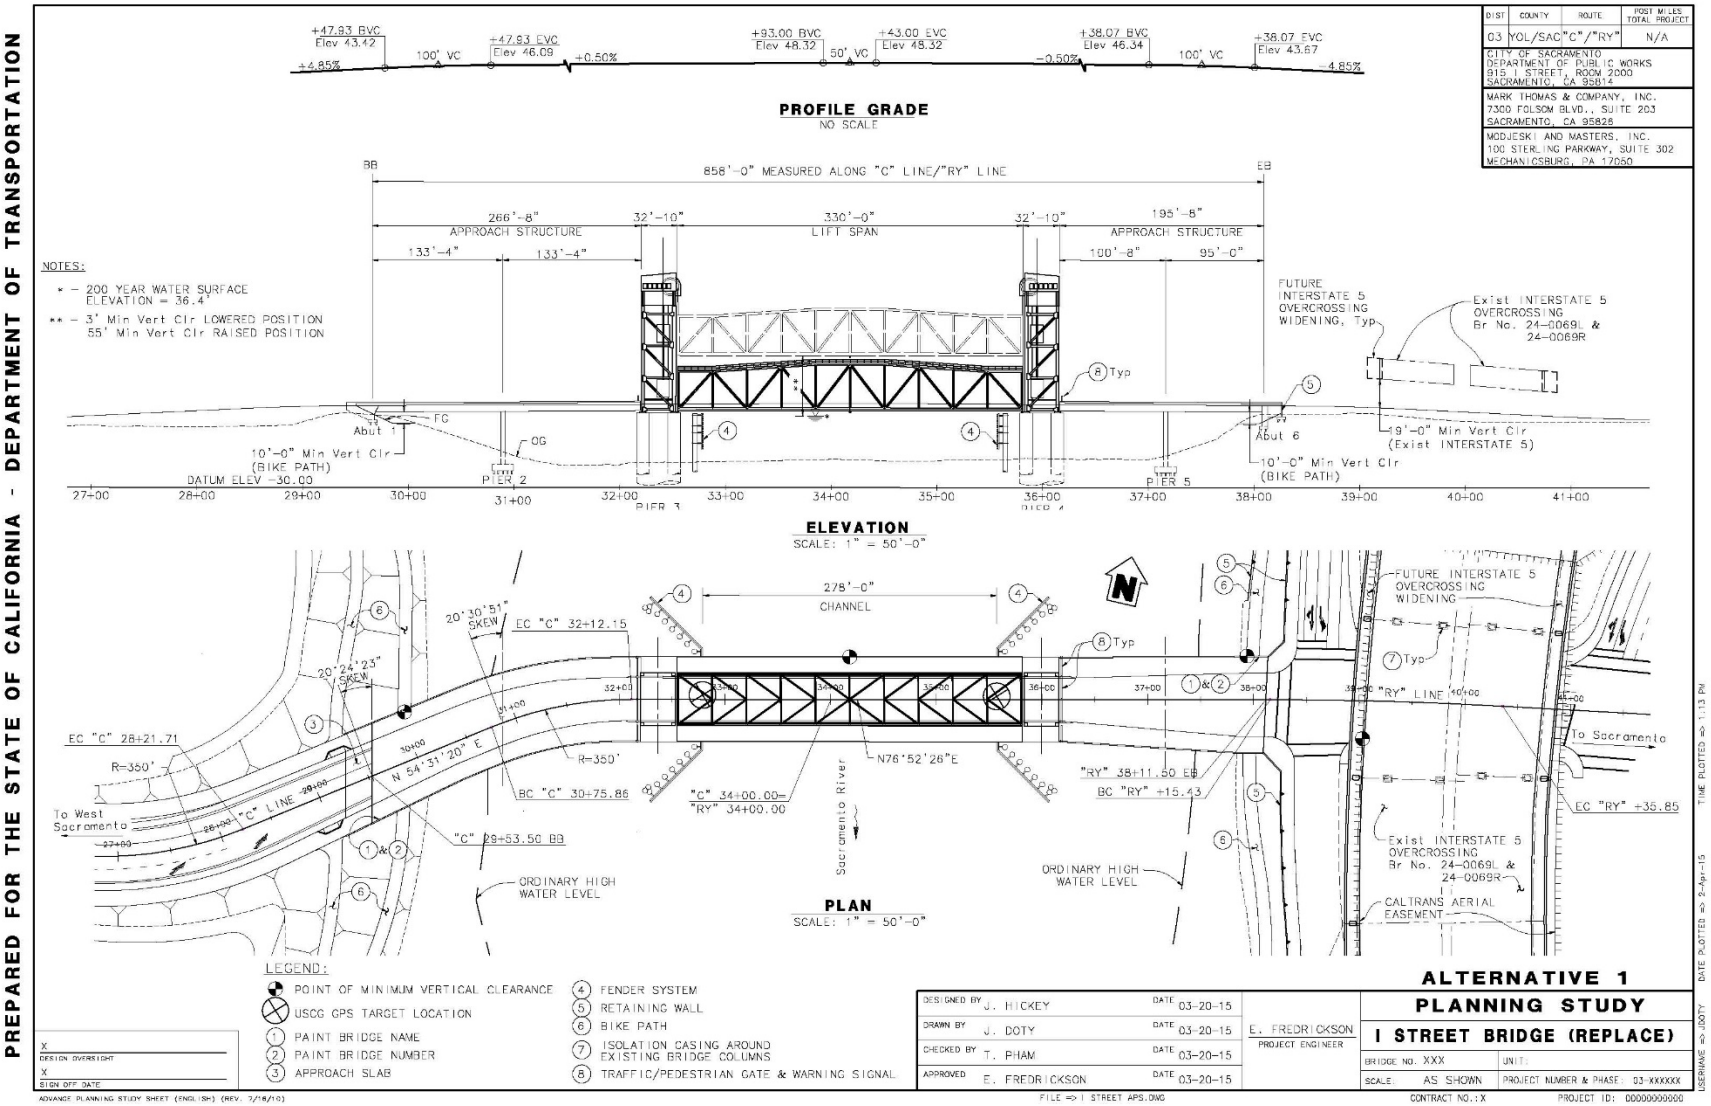

Figure 2. Project Drawing

HYDRAULIC MODEL

The MBK version of the U.S. Army Corps of Engineers (USACE) Sacramento River HEC-RAS hydraulic simulation model was used for this analysis. HEC-RAS software, developed by the USACE Hydrologic Engineering Center, is designed to perform one-dimensional hydraulic calculations for a full network of natural and constructed channels. Version 4.1 of HEC-RAS was used for the analysis presented herein.

The hydraulic model domain extends from Colusa and Oroville Dam in the north to Collinsville, near Suisun Bay, in the south.

The hydraulic model was set up in accordance with the following criteria defined in the California Urban Levee Design Criteria:

- Levees protecting urban areas are assumed to have a minimum crown elevation equal to the 1-in-200 AEP water surface elevation (WSE) plus 3 feet.
- Non-urban State/Federal Project levees are assumed to meet the authorized minimum elevation ("1957 Profile").
- Levees act as weirs and do not breach if overtopped.

HYDROLOGY

The hydrology used for this analysis was developed by USACE for the *Sacramento and San Joaquin River Basins Comprehensive Study* (Comprehensive Study). Updated hydrology for the American River and some of the smaller streams, including Dry Creek, Robla Creek, and Arcade Creek, was developed by USACE for the *American River Watershed Common Features General Reevaluation Report*. The hydrology for the American River assumed that the authorized Folsom Dam Joint Federal Project (JFP) and Water Resources Development Act of 1999 (WRDA 99) Common Features Project, currently under construction, are complete.

The Comprehensive Study hydrology consists of a number of hydrologic inflow data sets representing different storm "centerings." These centerings relied on historical storm patterns in the upstream basin to define the shape and magnitude of the flow contributions from each of the sub-basins, and were designed to stress specific locations within the system. The hydrologic data set used for this analysis was a storm centering designed to stress the Sacramento River at the latitude of the City of Sacramento.

DRAFT

MODELING OF THE PROJECT CONDITION

The proposed bridge is approximately located at River Station[1] (RS) 59.9. Three new cross sections were added to the hydraulic model so the bridge could be modeled:

1. RS 59.930, located about 110 feet upstream of bridge
2. RS 59.912, located about 10 feet upstream of bridge
3. RS 59.895, located about 10 feet downstream of bridge

The bridge site cross section from the AutoCAD file "C3D14_I Street-Alignments & Profiles.dwg" (from Mark Thomas and Company) was used for the three cross sections. To evaluate the hydraulic effects of a project, it is important that the project components are the only differences between the with- and without-project-conditions models; therefore the three additional cross sections were also added to the without-project-conditions model.

For this analysis, the fenders were assumed to be solid, effectively blocking the tower piers, and therefore representing a worst-case condition with regard to cross-sectional area. The width of the fender perpendicular to the river flow was estimated to be about 65 feet. The current design has a width for piers 2 and 5 of 5.5 feet. The design specifies that the low chord of the bridge deck will be at least 3 feet above the 1-in-200 AEP WSE, so it is not a factor in this analysis. The bridge deck as shown in the hydraulic model is for schematic purposes only and is not representative of expected design elevations. A schematic of the proposed bridge as modeled is provided in Figure 3.

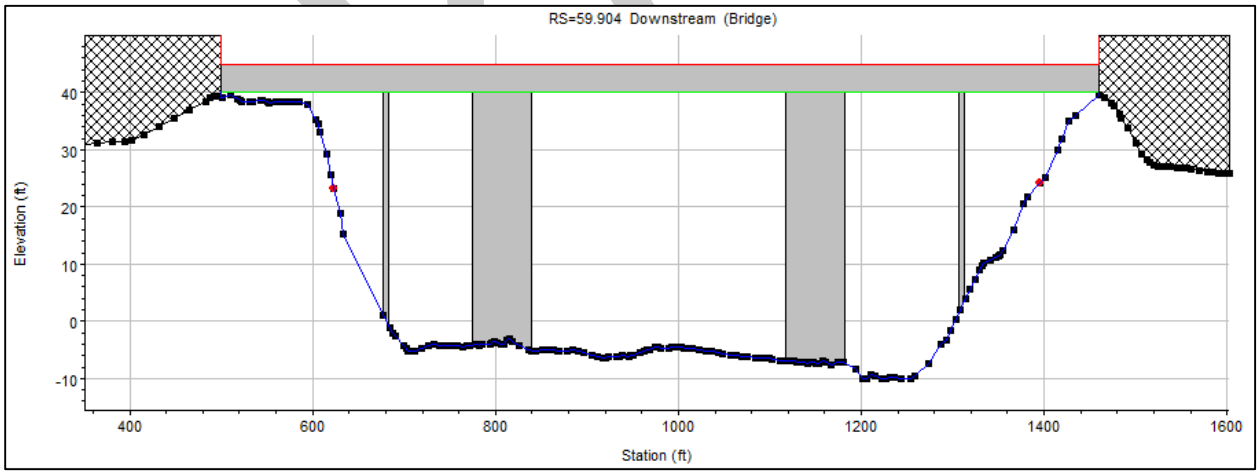

Figure 3. HEC-RAS Schematic of Proposed Bridge

The "Energy (Standard Step)" bridge modeling method was selected for both the low- and high-flow conditions. The Energy method is appropriate for the low-flow condition because there

[1] The river stationing used in this analysis is the river mile stationing developed by USACE for the Sacramento and San Joaquin River Basins Comprehensive Study.

are few piers, so pier blockage is expected to be a more significant factor than pier shape. The high-flow condition does not occur in this analysis so the method selected is not important.

The analysis took into consideration the potential for debris loading on the piers. In accordance with guidance provided to the Central Valley Flood Protection Board (CVFPB) for hydraulic analyses via letter dated July 21, 2014, the debris loading was assumed to be 2 feet in depth for a width twice the width of the pier. Figure 4 shows the bridge cross section with computed water surface and associated debris loading on the piers.

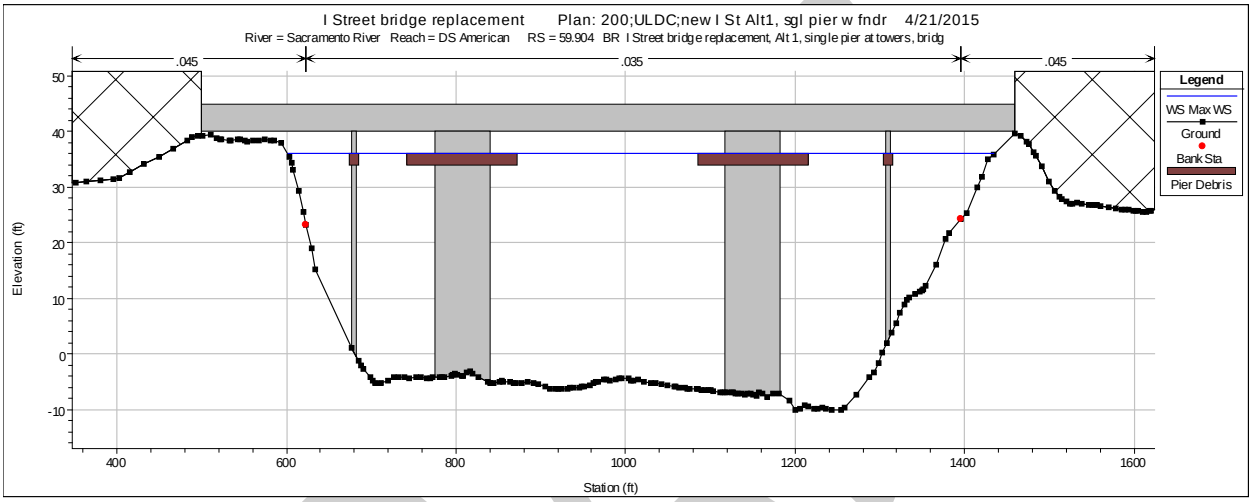

Figure 4. HEC-RAS Schematic of Proposed Bridge with Computed Water Surface and Bridge Pier Debris Loading

RESULTS

The proposed bridge results in a negligible increase in the peak WSE of 0.02 foot immediately upstream of the Project for all three of the flood events evaluated. Downstream of the Project there is a 0.06- to 0.07-foot reduction in the peak WSE. A profile plot of the computed change in water surface due to the Project for the Sacramento River from the Natomas Cross Canal to Sutter Slough is provided in Figure 5.

The analysis was also made without the fenders in place to evaluate the two configurations for the tower piers: either a single, solid pier or a group of four piers. For both these conditions, the greatest WSE increase was 0.01 foot. Downstream of the Project there was a reduction in the WSE that ranged from 0.03 to 0.06 foot.

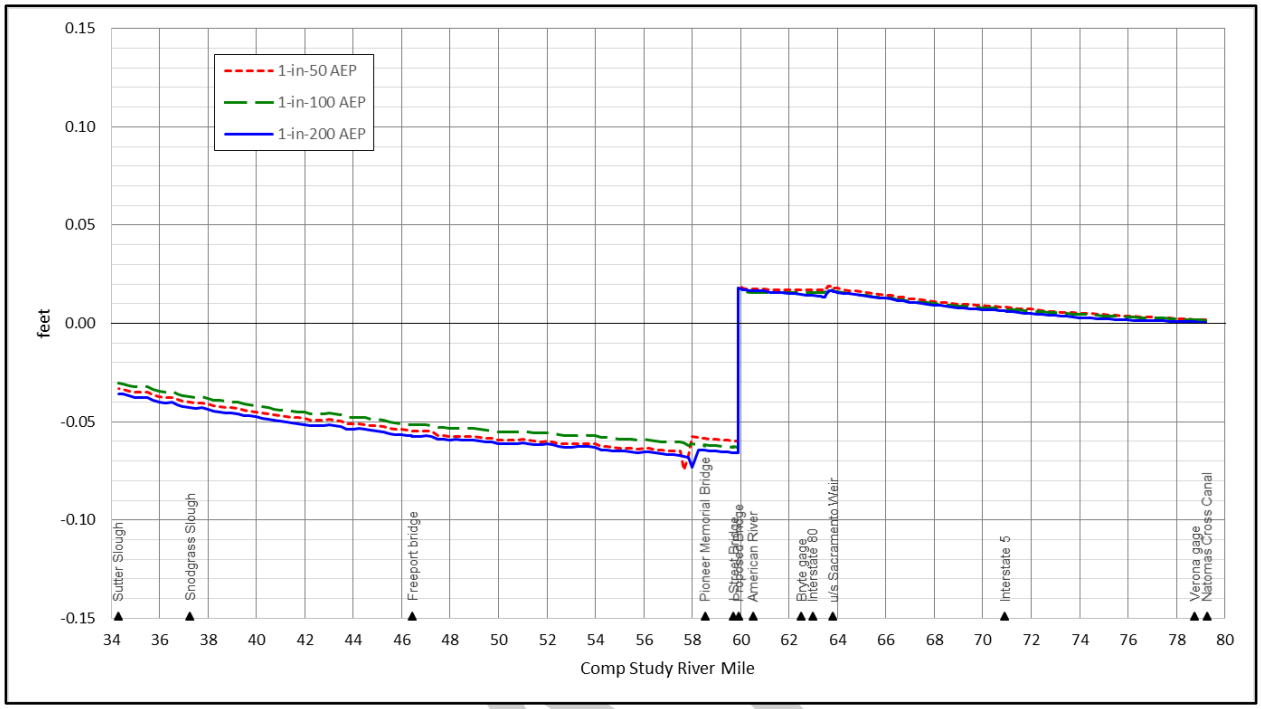

Figure 5. Project Effect on Maximum WSE in Sacramento River

The reduction in WSE downstream of the Project is due to a reduction in the peak flow in the Sacramento River downstream of the American River caused by the small increase in the WSE upstream of the Project. The increase in WSE upstream of the Project translates to an increase at the American River, thereby reducing the percentage of American River flow that goes downstream in the Sacramento River and increasing the percentage that flows upstream to the Sacramento Weir. This effect is shown by the peak flow summary provided in Table 1. As with the effect on the WSE, the effect on the flows is negligible.

DRAFT

Table 1. Effect of Project on Peak Flows at Sacramento River and American River Junction and in Sacramento Bypass

Flood Event (AEP)	Location	Peak Flow (cfs)		Change in Peak Flow	
		Without Project	With Project	cfs	Percent
1-in-50	Sacramento River downstream of American River	114,440	114,080	-410	-0.36%
	Sacramento River upstream of American River[1]	18,930	19,270	+340	+1.80%
	Sacramento Bypass	111,110	111,480	+370	+0.33%
1-in-100	Sacramento River downstream of American River	118,280	117880	-400	-0.34%
	Sacramento River upstream of American River[1]	19,400	19,760	+360	+1.86%
	Sacramento Bypass	114,690	115,020	+330	+0.29%
1-in-200	Sacramento River downstream of American River	131,030	130,580	-450	-0.34%
	Sacramento River upstream of American River[1]	45,520	45,930	+410	+0.90%
	Sacramento Bypass	149,790	150,170	+380	+0.25%

Key: AEP = annual exceedance probability; cfs = cubic feet per second
Notes:
1. The peak flow for this location is the peak going from the American River to the Sacramento Weir.

Subject: **INITIAL SITE ASSESSMENT (ISA)**
I Street Bridge Replacement Project
Sacramento and West Sacramento, California

Dear Mr. Siviglia,

Blackburn Consulting (BCI) prepared this Initial Site Assessment (ISA) for the I Street Bridge Replacement project located in Sacramento and West Sacramento, California. We completed this work in accordance with our agreement dated July 14, 2014. This report's purpose is to identify hazardous and potentially hazardous materials issues that may significantly impact the proposed project. This report addresses the property both within and immediately adjacent to the proposed improvement area.

As always, BCI appreciates the opportunity to be part of your team. Please call if you have questions or require additional information.

Sincerely,

BLACKBURN CONSULTING

Laura Long
Environmental Project Manager

EXECUTIVE SUMMARY

Blackburn Consulting (BCI) prepared this Initial Site Assessment (ISA) for Mark Thomas & Company (MTCo) for the I Street Bridge Replacement project which spans the Sacramento River between the cities of Sacramento and West Sacramento, California. The City of Sacramento, in cooperation with the City of West Sacramento and the California Department of Transportation (Caltrans), proposes to construct a new bridge over the Sacramento River to replace the vehicle crossing that is currently accommodated by the existing I Street Bridge in order to remove a series of functionally obsolete or structurally deficient bridges (i.e., approach structures). The new connection also would reduce future traffic congestion, improve operations and safety, serve multiple modes of transportation, and comply with current American Association of State Highway and Transportation Officials (AASHTO), Caltrans, and local agency design standards.

The project is subject to state and federal environmental review requirements because of use of federal Highway Bridge Program (HBP) funds from the Federal Highway Administration (FHWA). Accordingly, project documentation is being prepared in compliance with both the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA). The City of Sacramento is the lead agency under CEQA, with the City of West Sacramento as a responsible agency, and Caltrans is the lead agency under NEPA. The FHWA's other responsibilities for environmental review, consultation, and any other action required in accordance with applicable federal laws for this project will be carried out by Caltrans under its assumption of responsibility pursuant to 23 United States Code (USC) 327.

The purpose of this ISA is to identify Recognized Environmental Conditions[1] (RECs), Historical Recognized Environmental Conditions (HRECs), and potential RECs, collectively referred to herein as RECs, that may be present within and/or adjacent to the project limits. We prepared this report in general conformance with the American Society of Testing and Materials (ASTM) Standard E1527-13, *"Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process"*.

The following section summarizes in table format the key issues identified within and adjacent to the project limits. BCI further discusses the conditions in the body of this report.

Partial or Complete Acquisition Parcels with RECs

The project requires temporary and permanent property acquisitions along C Street, 3rd Street, and 2nd Street within the City of West Sacramento, and along Railyards Boulevard, Jibboom

[1] BCI uses the term Recognized Environmental Condition (REC) in general compliance with ASTM E1527-13, which defines the meaning as *"The presence or likely presence of any hazardous substances or petroleum products in, on, or at a property (1) due to any release to the environment, (2) under conditions indicative of a release to the environment or (3) under conditions that pose a material threat of a future release to the environment. The term is not intended to include de minimus conditions that generally do not present a threat to human health or the environment and generally would not be the subject of an enforcement action if brought to the attention of the appropriate regulatory agencies. Conditions determined to be de minimus are not recognized environmental conditions*."

Street, Bercut Drive, and I Street within the City of Sacramento. Comparison of these areas to identified REC sites, results in the following table of acquisition parcels with RECs that may impact project improvements.

For each acquisition parcel with known and/or potential RECs, Table 1 contains the assessor's parcel number (APN), address, current and/or former land use, REC description and PA/ED risk classification[2], and recommended action. Depending on the location of the right-of-way (ROW) to be acquired, site-specific assessments may be warranted for these parcels. In addition to the summary in Table 1, each of these sites are mapped on Figures 2 (A, B and C) and discussed in Section 4 of this report.

Table 1

Acquisition or Partial Acquisition Parcels With Known and/or Potential RECs

APN Address	Land Use Present/ Former	Figure	REC* Risk Class	Summary/Recommended Action*
010-102-005 205 2nd Street	Levee and access road/ Former historical development	Site A Figure 2a	Leach field, septic tank and/or buried heating oil tank ***Low***	Historical development located at this parcel from the 1890's until the 1970's. *Recommendation:* Plans for construction and/or partial acquisition should account for the potential to encounter a leach field, septic tank and/or buried heating oil tank
010-102-010 010-372-003 010-372-002 010-372-001 No street address	Levee, access road and water tower/ Former historical development	Site B Figure 2a	Leach field, septic tank and/or buried heating oil tank ***Low***	Historical development located at this parcel from the 1890's until the 1970's. *Recommendation:* Plans for construction and/or partial acquisition should account for the potential to encounter a leach field, septic tank and/or buried heating oil tank.
010-371-005 010-371-006 305 3rd Street (Old Police Building)	Vacant Lot/ Former Old Police Building	Site C Figure 2a	Soil (nickel and lead) and groundwater (nickel, lead, cadmium, chromium) impacts ***High***	Known impacts to soil and groundwater, however, sampling locations are not within the proposed ROW improvement area for this project. *Recommendation*: Conduct a Phase II assessment within the proposed acquisition area.

[2] Risk Class is based on the Caltrans Project Development Procedures Manual (Chapter 18, February 2006) guidelines, which traditionally attempt to rank risk into high, medium and low, based on the potential impact on an objective.

Table 1

Acquisition or Partial Acquisition Parcels With Known and/or Potential RECs

APN Address	Land Use Present/ Former	Figure	REC* Risk Class	Summary/Recommended Action*
010-482-011 301 C Street and 300 3rd Street	Vacant Lot/ Former service station (Dorris Shell Station)	Site G Figure 2a	Potential USTs, TPH-g, TPH-d, TPH-mo ***High***	No record of the presence and/or removal of USTs at the former service station. *Recommendation*: Conduct site inspection, in-depth record review and owner interview; if no additional information is found, conduct a Phase II assessment within the proposed acquisition area.
010-101-004 217 3rd Street	Residential /Former laundry	Site H Figure 2a	Solvents ***Low***	The parcel is identified as a "laundry facility" on the 1915 Sanborn Map. *Recommendation*: Conduct site inspection and owner interview; a Phase II assessment may be recommended based on findings.
Sacramento Railyards	Railyards development/ Northern Shop Study Area (NSA)	Site M Figure 2b	Known soil impacts and potential groundwater impacts. TPH, VOCs, SVOCs, metals ***High***	Soil within the NSA is certified and DTSC approved Remedial Goals have been achieved. Groundwater assessment and remediation activities are ongoing and are the responsibility of UPRR. *Recommendation*: Conduct all operations in compliance with the LUC of 2015 and Railyards Soil and Groundwater Management Plan. Impacts to groundwater have not been established by UPRR, therefore, a Phase II assessment to the depth of construction is recommended. All Phase II sampling plans must be approved by DTSC.
001-0190-007 001-0210-018 002-0010-023 Adjacent to Jibboom Street	Levee, bike path, Jibboom Park/Former Associated Metals (Jibboom Junkyard), warehouse	Sites O, P and Q Figure 2b	TPH, metals, PCBs ***High***	APN 001-0190-007 may be within the former Associated Metals footprint. APN 001-0210-018 and APN 002-0010-023 are within the footprint historical industrial development. *Recommendation:* Conduct a Phase II assessment within the proposed acquisition area.

Table 1				
Acquisition or Partial Acquisition Parcels With Known and/or Potential RECs

Sacramento Railyards	Roadway/ Former Manufactured Gas Plant (MGP)	Site N Figure 2b	Soil and Groundwater impacted with TPH, metals, VOCs, and SVOCs ***High***	Soil and groundwater conditions are characterized in the 2015 Final MGP RIR. Remediation of soil and groundwater is on-going. Impacts in the upper 10-feet are minimal; however, areas adjacent to footings and support columns for Jibboom Street and I-5 may be significantly impacted. *Recommendation:* If remediation is complete and soils are certified prior to construction, comply with applicable LUC and/or guidance documents. If site characterization is not complete, conduct a Phase II assessment within the depth and area of construction impacts.
Sacramento Railyards Existing I Street Bridge viaduct	Sacramento Station Study Area (SSA)	Site X Figure 2c	Soil impacted with metals and TPH ***Medium***	Soil within the SSA is certified and the DTSC approved Remedial Goals have been achieved. Groundwater assessment and remediation activities are ongoing and are the responsibility of UPRR. Project improvements are shallow and are not expected to extend to groundwater. *Recommendation*: Conduct all operations in compliance with the LUC of 2015, and Railyards Soil and Groundwater Management Plan.
Caltrans ROW at Bridge approach from C Street	Caltrans ROW bridge approach and 2nd Street south of C Street/vacant lot	Site Y Figure 2a and 2c	Adjacent to Firehouse Block with known soil and groundwater impacted with metals ***Medium***	Additional ROW will be acquired along C Street at this parcel which is currently developed with the I Street Bridge approach. Removal of existing bridge approach is to occur at this site. Adjacent to a site with known soil and groundwater contamination. *Recommendation*: Conduct a Phase II assessment for metals within the depth of construction impacts.

*Applicable Abbreviations and Acronyms are listed in table format preceding the Executive Summary.

Adjacent and General Vicinity REC Sites

We identified sites with RECs which, based on the preliminary plan alternatives, are located immediately adjacent to partial or complete acquisition parcels or existing ROW, as well as potentially significant REC sites in the general vicinity of the project alignment. Based on the location of the proposed project and currently available information, none of these parcels will require partial or complete acquisition for this project. However, if plans for ROW or acquisition change to include one or more of these properties, further review and investigation of potential hazardous materials or petroleum hydrocarbon impacts is recommended.

These sites are summarized in Table 2 below and are further discussed in the body of the report. In addition to the summary in Table 2, each of these sites are mapped on Figures 2 (A, B and C).

Table 2

Parcels Adjacent to Acquisition Parcels and/or Existing ROW With Known and/or Potential RECs

APN Partial Acquisition Address	Land Use Present/ Former	Figure	REC* Risk Class	Summary/Recommended Action*
010-371-004 317 3rd Street Adjacent parcel acquisition	Abandoned Fire Station/Former Fire and Police Station	Site D, Figure 2a	Soil (nickel and lead) and groundwater (nickel, lead, cadmium, chromium) ***High***	Known impacts to soil and groundwater. *Recommendation:* If ROW acquisition or project improvements include this parcel, conduct a Phase II assessment within the proposed acquisition/improvement area.
010-371-003 319 3rd Street Adjacent parcel acquisition	Vacant lot/ Former Capitol Plating facility	Site E, Figure 2a	Soil (nickel and lead) and Groundwater (nickel, lead, cadmium, chromium, solvents) contamination ***High***	Former metal plating facility. Known impacts to soil and groundwater. *Recommendation:* If ROW acquisition or project improvements include this parcel, conduct a Phase II assessment within the proposed acquisition/improvement area.

*Applicable Abbreviations and Acronyms are listed in table format preceding the Executive Summary.

General Contamination Issues

Asbestos Containing Materials (ACM) and Lead Based Paint (LBP) at the existing I Street Bridge and Approach Structures

The United States Environmental Protection Agency, National Emission Standards for Hazardous Air Pollutants (USEPA NESHAP), 40 CFR Part 61 – Nov 20, 1990, requires an owner or operator of a demolition or renovation project to thoroughly inspect the affected facility or part of the facility where the demolition or renovation operation will occur for the presence of ACM prior to the commencement of that project.

The I Street Bridge and its associated approaches are proposed for demolition or modification. BCI had the bridge and approaches surveyed for ACM and LCP by Entek Consulting Group (Entek), a California Certified Asbestos Consultant and certified Lead Inspector/Assessor. Findings of the surveys are summarized below and the complete Hazardous Materials Survey Final Report (dated 14 May 2015) is in Attachment 1. The report concluded that ACM is present in the railing gaskets and the fastener sealants. Specifics pertaining to individual materials are presented in the attached report.

Entek investigated existing paints and applied coatings associated with the bridge to determine if lead was present in these materials. Three paints/locations were determined to have paint containing more than 5,000 ppm lead and are classified as lead-based paint; these are:

1. Silver paint on metal bridge structure
2. Black paint on metal bridge structure
3. White paint on metal northeast approach

In addition, the gasket located at the base of the light boxes on the northeast approaches was determined to be pure lead. Precaution should be used when handling this material.

Consequently, any demolition or modification of the bridge and/or approach structures within the project area will require that an appropriate ACM and Lead Compliance Plan be developed. Abatement of LCP and/or ACM shall be conducted, as necessary, by contractors certified to perform such work in accordance with state and federal regulations.

ACM/LCP in Buildings/Residences

The ACM/LCP assessment did not include buildings within the project limits. Typically pre-demolition surveys for occupied buildings are conducted at a later date. Any structure constructed pre-1980 has the potential to contain ACM/LCP materials

Recommendation: Any structure identified for modification and/or demolition that was constructed pre-1980, must be surveyed by a certified Asbestos Inspector prior to building demolition/modification.

Aerially Deposited Lead (ADL)

ADL has been found to occur in soils adjacent to highways and high use roadways. The lead is presumably from the historical use of leaded gasoline and subsequent exhaust emissions. There is potential for encountering ADL during construction and grading activities within the proposed project limits in West Sacramento along C Street, 2nd Street and at the bridge approach/viaduct leading from C Street. A majority of the area adjacent to C Street is covered sidewalk; therefore, an ADL assessment would be limited to areas with exposed soils in that area.

There is potential to encounter ADL during construction and grading activities within the proposed project limits in Sacramento at the bridge approach/viaduct leading from I Street, and along Jibboom Street and Bercut Drive. These roadways have been present in various alignments since 1916 and, therefore, have the potential to be impacted with ADL. BCI conducted an ADL Assessment in 2009 for portions of Jibboom Street north of the current project limits. The 2009 Assessment results indicate that soils from the tested area would be classified as either non-hazardous or as soil acceptable for management in accordance with DTSC and RWQCB.

In addition, the bridge landing will be located within the Sacramento Railyards. This area is not likely to exhibit elevated concentrations of ADL from typical automobile emissions; however, historical operations at the Railyards has impacted the site with metals including lead. Approved total lead concentrations for soils within the railyards will be guided by the Remediation Goals set for each study area by DTSC.

Recommendation: Conduct an ADL study within the project limits at the following locations:

- Along unpaved areas of C Street in West Sacramento
- 2nd Street in West Sacramento
- Adjacent to and below the bridge approach/viaduct in West Sacramento
- Along Jibboom Street
- Adjacent to and below the bridge approach/viaduct in Sacramento

Within the Railyards property, conduct all operations in compliance with the LUC of 2015, and Railyards Soil and Groundwater Management Plan.

1. INTRODUCTION

In accordance with our proposal dated March 8, 2013, Blackburn Consulting (BCI) prepared this ISA for proposed improvements at the I Street Bridge Replacement Project in Sacramento and West Sacramento, California. The purpose of this assessment is to identify recognized environmental conditions[3] (RECs), potential RECs, and historical RECs, herein collectively referred to as "RECs" that may affect the proposed property acquisition and/or project construction. We prepared this report in general conformance with the ASTM Standard E1527-13, *Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process*.

To conduct this ISA, BCI:

- Conducted a site visit to observe current land use and indications of potential contamination for those parcels that may be impacted by improvements, and view publicly accessible portions of the adjacent properties;
- Reviewed prior environmental reports prepared for the subject area;
- Reviewed historical aerial photographic, topographic, and Sanborn maps and City Directory coverage of the site and surrounding properties to identify past and present land use for indications of potential sources of contamination;
- Reviewed available California Department of Toxic Substances Control EnviroStor and State Water Resources GeoTracker online database information;
- Reviewed available case files at Yolo County Environmental Health Services (YCEHS), Sacramento County Environmental Health Department (SCEHD), and Central Valley Regional Water Quality Control Board (RWQCB);
- Reviewed commercial database of federal, state, and county records for indications of the use, misuse, or storage of hazardous materials at or adjacent to the acquisition parcels. The database was provided by Environmental Data Resources, Inc. (EDR) of Southport, Connecticut; and
- Reviewed the general site geology, ground water, and soil conditions through published maps and literature.

[3] BCI uses the term Recognized Environmental Condition (REC) in general compliance with ASTM E1527-13, which defines the meaning as *"The presence or likely presence of any hazardous substances or petroleum products in, on, or at a property (1) due to any release to the environment, (2) under conditions indicative of a release to the environment or (3) under conditions that pose a material threat of a future release to the environment. The term is not intended to include de minimus conditions that generally do not present a threat to human health or the environment and generally would not be the subject of an enforcement action if brought to the attention of the appropriate regulatory agencies. Conditions determined to be de minimus are not recognized environmental conditions*."

2. PROJECT DESCRIPTION AND LOCATION

2.1 Description and Location

The City of Sacramento, in cooperation with the City of West Sacramento and Caltrans, proposes to construct a new bridge over the Sacramento River to replace the vehicle crossing that is currently accommodated by the existing I Street Bridge in order to remove a series of functionally obsolete or structurally deficient bridges (i.e., approach structures). The new connection also would reduce future traffic congestion, improve operations and safety, serve multiple modes of transportation, and comply with current AASHTO, Caltrans, and local agency design standards.

The project is subject to state and federal environmental review requirements because of use of federal HBP funds from the FHWA. Accordingly, project documentation is being prepared in compliance with both CEQA and NEPA. The City of Sacramento is the lead agency under CEQA, with the City of West Sacramento as a responsible agency, and Caltrans is the lead agency under NEPA. The FHWA's other responsibilities for environmental review, consultation, and any other action required in accordance with applicable federal laws for this project will be carried out by Caltrans under its assumption of responsibility pursuant to 23 USC 327.

The proposed project is located over the Sacramento River between the cities of Sacramento and West Sacramento, approximately 1,000 feet north of the existing I Street Bridge. The project limits starting within the City of Sacramento consist of Railyards Boulevard from 200 feet east of Bercut Drive on the east, continuing west over the Sacramento River into the City of West Sacramento along C Street, and terminating approximately 100 feet west of the 5th Street intersection. The project limits also extend along Bercut Drive approximately 500 feet north of Railyards Boulevard, along Jibboom Street 550 feet north of Railyards Boulevard and 300 feet south of Railyards Boulevard, along 3rd Street 50 feet north and south of C Street, along 4th Street 50 feet north and south of C Street, and along 5th Street 50 feet north and south of C Street. The total length of the project is approximately 0.42 mile along C Street and Railyards Boulevard.

This project is included in the Sacramento Area Council of Governments (SACOG) 2035 Metropolitan Transportation Plan/Sustainable Communities Strategy (MTP/SCS).
The project requires temporary and permanent property acquisitions along C Street, 3rd Street, and 2nd Street within the City of West Sacramento and along Railyards Boulevard, Jibboom Street, Bercut Drive, and I Street within the City of Sacramento.

Along C Street, temporary and permanent acquisitions would be required along the south side of the roadway to accommodate the construction of standard shoulders, bike lanes, and sidewalks—from the intersection of 4th Street to the Sacramento River.
Along 3rd Street and 2nd Street, temporary and permanent acquisitions would be needed from the Union Pacific Railroad on the south, to just north of the B Street intersections, for construction of the proposed roadway and levee improvements.

Along Railyards Boulevard, Jibboom Street, and Bercut Drive, temporary and permanent acquisition would be needed from the current state-owned right-of-way for I-5, for construction of the roadway. In addition, temporary and permanent acquisitions would be needed along Jibboom Street for the proposed temporary detour road and Class I bikeway improvements. Temporary acquisition would be required along the existing I Street connection to facilitate removal of the existing viaduct structures. Due to the limited space available in Old Sacramento, it is anticipated that construction activities would occur from the parking lot at the intermodal station.

Figure 1 is a Vicinity Map and Figure 2 is a Site Plan of the proposed project area.

2.2 Current Land Use

West Sacramento: The project area consists of existing roadway, curb, gutter, and/or sidewalk areas associated with C Street from 6th Street to 2nd Street. This area is a mixed use area with commercial (market, deli), residential, and vacant lots. The new bridge approach extends across the existing levee which is generally open space with a gravel access road. A small, fenced area around the West Sacramento River Walk Tower (which will be relocated as part of this project) is located on the west side of the levy. This portion of the site is bordered by the Sacramento River to the east. The project area also includes the removal of the existing bridge approach from C Street and the removal of a portion of 2nd Street.

Sacramento: The project area consists in part, of existing levee, roadway, curb, gutter, and/or bike paths associated with Jibboom Street. Project improvements also include a proposed connection to Railyards Boulevard in the Sacramento Railyards (Railyards), where the connection to the new bridge will be completed beneath the existing underpass at I-5. The remaining portion of the project is developed with I-5, Jibboom Street and the southern connection to Bercut Drive. The area to the north along Jibboom Street is developed with the historical PG&E building, water intake facilities, service stations, and restaurants; and along Bercut Drive with the Sacramento River Treatment Plant, and Communication Center. The areas to the south and east are part of the 240-acre Railyard site. The site is bordered by the Sacramento River to the west.

2.3 Topography

West Sacramento: The topography within and surrounding the project area is generally flat. The site elevation is approximately 30 to 39 feet above mean sea level (msl) based on Google Earth Imagery, dated July 2, 2014.

Sacramento: The topography within the study area is generally flat with the site elevation approximately 29 to 36 feet above msl based on Google Earth Imagery, dated July 2, 2014.

2.4 General Geologic Conditions

The site lies within the Great Valley Geomorphic Province of California, which is a large, elongate, northwest-trending structural trough. The Province is subdivided into two major

divisions designated the Sacramento and San Joaquin Valleys. These valleys have been filled to their present elevation with thick sequences of sediment, ranging in age from Jurassic to present day, creating a nearly flat-lying alluvial plain that extends from the Tehachapi Mountains in the south to the Klamath Mountains in the north. The western and eastern boundaries of this province are formed by the California Coast Ranges and the Sierra Nevada, respectively. The study area is located on an alluvial plain approximately 0.4 miles south-southeast of the confluence of the American and Sacramento Rivers. The underlying deposits are mapped by Wagner et al. (1981) as Quaternary Levee and Channel deposits which are expected to consist of interbedded sand, silt, clay, and some gravel layers.

2.5 Surface Water, Groundwater and Wells

West Sacramento: The prevailing groundwater flow direction in West Sacramento is to the northeast, though flow directions vary both locally and seasonally. The study area is adjacent to the Sacramento River, where groundwater flow direction is controlled by the Sacramento River height, with flow switching 180 degrees toward and away from the river. This would suggest an alternating east-west flow direction in the general project area. BCI reviewed groundwater level data made available at California Department of Water Resources (DWR) website www.water.ca.gov/waterdatalibrary. The groundwater beneath the site rises to within four feet of the ground surface for up to six months of the year. Depth to groundwater during the rest of the year is approximately 12-28 feet below ground surface. Surface/storm water is directed by sidewalk curb and drains. The general flow direction is to the south and east. One Federal USGS well is located within the project limits. This well is adjacent to the West Sacramento River Walk water tower.

Sacramento: Groundwater beneath the site is hydraulically connected to the Sacramento River. The river serves as a hydraulic connection, and presumably a barrier, to the potable groundwater that is on the western side of the Sacramento River. Flow direction is presumed to fluctuate semiannually according to the river stage (similar to the West Sacramento side). BCI reviewed general groundwater level data made available at the DWR website www.water.ca.gov/waterdatalibrary and site specific groundwater monitoring well data presented in the Final Remedial Investigation Report, Manufactured Gas Plant Study Area (MGP RIR), dated April 2015. The groundwater beneath the site historically rises to within five feet of the ground surface for up to six months of the year. Depth to groundwater during the rest of the year is approximately 15-30 feet below ground surface. Groundwater elevation is also influenced by groundwater recharge due to infiltration of water lost from the Sacramento County water filtration plant.

Natural surface water flow directions have been altered by construction of roadway and structures. The general flow direction appears to be to the south and west. There are three Federal USGS wells, one Federal Water Supply System, and ten State Database wells located within a one mile radius of the project area. In addition, multiple groundwater monitoring wells related to on-going site characterization are within and adjacent to the Railyards.

2.6 Historic Land Use

I Street Bridge: The first bridge across the Sacramento River was built in 1858 for auto traffic. The bridge extended from Broad Street (now abandoned) in Sacramento to D Street in West Sacramento. In 1870, the California Pacific Railroad Company (later Southern Pacific) constructed the first railroad bridge 400 feet from the 1858 bridge. In 1893, Southern Pacific and the counties of Sacramento and Yolo began the construction of a joint bridge for railroad and highway use, which was completed in 1895 (Red Bridge) This bridge was situated about 300 feet down-stream of the current day railroad-highway bridge. The Red Bridge approach was at East Street in Washington (West Sacramento). This bridge was removed as soon as traffic was routed over the new and present structure built in 1911.

West Sacramento: The first settlers came to the area during the early 1840's. In 1849, the area was surveyed and divided into township parcels that became known as Washington. Washington was primarily dedicated to agriculture although, in addition to agriculture, from 1864 to 1866 the Pacific Coast salmon cannery was present along the West Sacramento River walk. In 1914, the township was renamed Broderick.

Sacramento: During the mid-1800s the project area was developed as a locomotive maintenance and rebuilding facility, among other functions. During the mid-1800s the area north of the Railyards was primarily undeveloped due to the swampy characteristic of the area, and the presence of the American River channel which extended through the project limits. Sutter Lake existed immediately south and east of the project and a promontory from Sutter Lake to the American River, named Slater's Addition was shown to exist in 1848. This promontory was crisscrossed by a number of streets (Sycamore, First, Broad, Lake) that no longer exist. Many ships anchored off Slater's Addition giving rise to the name of Jibboom Street for its waterfront area. This area did not develop as rapidly as the central business district between I and M Streets or the Standard Pacific Railroad (SPRR) which developed along Sutter Lake. In 1868, to prevent flooding, the American River was rechanneled to its present day configuration. By 1910, Sutter Lake had been filled and the Railyard was further developed which led to the development of the area to the north.

2.6.1 Aerial Photograph Review

The following aerial photos were reviewed:

1854 Photo Map Overlain on 1937 Aerial, Scale unavailable
1937 Photo by Laval, Scale 1"=500'
1947 Photo by USGS, Scale 1"=500'
1957 Photo by Cartwright, Scale 1'=500'
1964 Photo by Cartwright, Scale 1"=500'
1971 Photo by Cartwright, Scale 1"=500'
1984 Photo by USGS, Scale 1"=500'
1993 Photo by USGS, Scale 1"=500'
1998 Photo by EDR, Scale 1"=500'

2005 Photo by EDR, Scale 1"=500'
2006 Photo by EDR, Scale 1"=500'
2009 Photo by EDR, Scale 1"=500'
2010 Photo by EDR, Scale 1"=500'
2012 Photo by EDR, Scale 1"=500'

We reviewed historic aerial photography to identify conditions that may indicate potential hazardous materials conditions within or adjacent to the project limits. Aerial photographs are provided in Appendix A. The following summary highlights these findings.

West Sacramento

1937: The I Street Bridge approach (railroad and automobile) is located along D Street with the main approach connecting to 3rd Street. C Street is developed with multiple structures interspersed with trees. The block north of C Street between 3rd and 4th Streets is primarily vegetation with one large building in the center of the parcel. The Firehouse block, south of C Street, is developed with multiple structures between 2nd and 3rd Streets. The area between the river and 2nd Street is developed with multiple cabin-like structures. Three service stations are present at the intersection of 5th and C Streets. The parcel at the southwest corner of C and 3rd Streets is developed with what appears to be a service station.

1947: Additional structures are located along the C Street corridor. The vegetated parcel is cleared and now has multiple large structures present.

1957: No significant changes.

1964: The automobile approach to I Street Bridge has been realigned to C Street along an inverted S-curve to D Street between 3rd and 2nd Streets. The east half of the block where the new bridge approach was constructed has been cleared. Very little vegetation remains.

1971: No significant changes.

1984: Poor photography resolution.

1993: The cabin structures adjacent to the river are no longer visible. A large water tank north of B Street is visible. The service station at the southwest corner of C and 3rd Streets is gone.

1998: Two large structures are no longer visible at the Firehouse block. The block between 3rd and 4th Streets north of C Street is cleared. The site at the southeast corner of C and 5th Streets is cleared. The southwest quadrant of the block between 2nd and 3rd Streets, north of C Street, is cleared; this parcel historically housed two laundry facilities.

2005: Multiple structures are visible in the previously cleared parcel north of C Street between 3rd and 4th Streets. An additional structure is cleared from the Firehouse block.

2006: No significant changes.

2009: Additional development within the project limits.

2010: No significant changes.

2012: No significant changes.

Sacramento

1854: A map (1854) of the American River is overlain on a 1937 Aerial Photograph. The former river channel of the American River is identified. The former confluence of the Sacramento and American Rivers is located along the north side of the Railyards immediately south of the existing water treatment plant.

1937: The Jibboom Street alignment connects to the present day Bercut Drive in an arcing ninety degree bend. A water treatment facility exists east of Bercut Drive (original Jibboom Street alignment). Multiple railroad tracks and switch tracks are present. One structure is visible west of Jibboom Street just north of where the new bridge alignment is located. A second large structure is located where the proposed Bercut intersection is planned. A large warehouse/dock area is located south of the proposed bridge approach on the riverbank west of Jibboom Street. A faint outline of the promontory that used to extend into the Sacramento River is visible. The American River is in its present day alignment.

1947: Multiple structures associated with the Railyards are south of the curve connecting Jibboom Street and Bercut Drive. The original Jibboom Street alignment (now Bercut Drive) is visible. Multiple structures are located between the river and Jibboom Street.

1957: A large structure is located immediately north of the large curve connecting Jibboom and Bercut (approximately ¼ mile north of the project alignment). The area surrounding the structure appears to be a junk yard which extends from Bercut on the east and the river on the west.

1964: The junkyard has a large quantity of materials/debris located on site.

1971: I-5 exists in its current alignment. Bercut Drive is terminated south of the water treatment facility. Jibboom is realigned in its present alignment. The junkyard is cleared. All of the structures west of Jibboom are no longer visible with the exception of one structure at the river's edge. The Railyard appears active with some operations extending under the elevated I-5 roadway.

1984: Poor photography resolution.

1993: Portions of the Railyard are cleared.

1998: Additional clearing in the Railyard. Several large buildings remain within the project limits.

2005: The new water intake for the water treatment facility is visible northwest of the project limits. The Railyard is cleared within the project limits with the exception of the railroad tracks.

2006: The Railyard is cleared further and appears to have stockpiles located throughout the northern portion of the site. The railroad tracks are removed.

2009: The stockpiles are no longer visible.

2010: The precursor to Railyard Boulevard is visible.

2012: No significant changes.

2.6.2 Topographic Map Review

Topographic maps reviewed include 7 ½ -minute quad maps from 1916, 1949, 1954, 1967, 1975, 1980 and 1992; and a 15-minute quad map from 1907. Copies of topographic maps are provided in Appendix B. This summary includes the noted changes within and adjacent to the project limits as recorded on the maps:

West Sacramento

1907: West Sacramento is identified as Washington/Broderick. A levee exists adjacent to the Sacramento River. Structures are present on both sides of the levee. The Southern Pacific railroad alignment along D Street ends at 5th Street in a spur line. The railroad track jogs southeast from D Street to E Street and continues to a bridge crossing. The bridge crossing is identified as a railroad crossing. The bridge crosses the Sacramento River extending from the approach at E Street to the Sacramento Railyards. The I Street Bridge is not present. Multiple structures are visible along the roads (present day C Street and east of 2nd Street) within the project alignment.

1916: A second bridge, the I Street Bridge, extends across the Sacramento River from D Street to the Sacramento Railyard. The existing Tower Bridge is identified as a railroad crossing and is located south of the other two bridges.

1949: The area is identified as Broderick. I Street Bridge is identified by name. The bridge extending from E Street is no longer present. The approach to the I Street Bridge is modified to extend north on 3rd Street between D and C Streets. C Street is modified as Highway 16/24 as it extends west of 5th Street, curving to the southwest until it runs parallel to the railroad tracks. Several large structures exist on the north and south sides of C Street.

1954: Highway 16/24 is an improved road that extends from west of 6th Street, across the Sacramento River and into the Sacramento Railyards. Few structures are included on this map with the exception of one large structure between 3rd and 4th Streets immediately north of C Street. A small lake is present north of the levee access road.

1967: The small lake is no longer visible. A water tower is identified east of 2nd Street. Borrow Pits are located north of the project limits.

1975: Highway 16/24 is an improved road that extends from west of 6th Street, across the Sacramento River and into the Sacramento Railyards. Few structures are included on this map.

1980: The Old Sacramento State Historical Park is identified south of the project limits.

1992: No significant changes.

Sacramento

1907: The project area is developed with a north-south road. Multiple structures exist on both sides of the roadway. Two large structures are at the river's edge immediately south of the proposed bridge approach. Railroad tracks are visible to the north. A wide area of land (promontory) extends into the Sacramento River at the proposed bridge approach. A railroad bridge crossing is identified north of the present day I Street Bridge. The bridge crosses the Sacramento River extending from the approach at E Street to the Sacramento Rail yards. The I Street Bridge is not present.

1916: A second bridge, the I Street Bridge, extends across the Sacramento River from D Street to the Sacramento rail yard. The Tower Bridge is identified as a railroad crossing and is located south of the other two bridges. A railroad spur is identified adjacent to the river and runs from the I Street Bridge to an unimproved Bercut Drive. Railroad tracks are visible running east-west both to the north and south of the project limits.

1949: I Street Bridge is identified by name. The bridge north of I Street Bridge is no longer present. A Water Intake Tower and Filtration Plant are identified. The north-south road is improved as a major roadway. The promontory no longer exists. An unimproved Jibboom Street is present adjacent to where the promontory previously extended into the river. The Railyard is developed with multiple switch tracks and structures.

1954: No significant changes.

1967: Jibboom Street is unimproved. Bercut Drive connects to the north-south roadway. The large buildings adjacent to the river are no longer present. The Filtration Plant is more developed. Additional railroad tracks are visible within the project limits. One large structure is located at the bridge approach. I-5 is present but not identified by name.

1975: Jibboom Street connects to the north-south roadway. Bercut Drive terminates south of the filtration plant.

1980: No significant changes.

1992: A majority of the railroad tracks are no longer present.

2.6.3 Historical Sanborn® Map Review

West Sacramento

EDR provided Sanborn® Maps from 1895, 1915, 1950, 1952, 1957, 1960, 1968 and 1970 for the project and surrounding area. Appendix C contains copies of the Sanborn® Maps. This review summary includes the noted changes within and adjacent to the project area as recorded on the maps:

1895

- A *Four Way Bridge*, *Watchman* building and *Private Stables* are identified directly across the Sacramento River from the *Pioneer Mills Sperry Flour Company*.

1915

- A *Boat Building*, *Steel Water Tank* and multiple *Dwellings* are located along the east side of 2nd Street.
- *Town Hall* is on the southeast corner of 3rd and C Streets.
- *Washington Public School* is along C Street between 3rd and 4th Streets.
- A *Chinese Laundry* is located at 225 3rd Street. An adjacent structure containing a *washer/dryer* symbol is located south of the laundry. A second *laundry* is located at 217/219 3rd Street.
- The approach to the *Sacramento River Bridge* is identified along D Street.

1950

- The *Dwellings* east of 2nd Street and south of C Street are replaced by forty-six *cabins*.
- A *Fire Department* and *Plating Works* are located south of *Town Hall* at the southeast corner of 3rd and C Streets.
- The *washer/dryer* adjacent to the laundry are no longer present.

1952

- The *Town Hall* site is cleared.
- A *Gas & Oil* structure is identified at the southwest corner of 3rd and C Streets.

1957

- A new structure, with an indiscernible label, is located where *Town Hall* was previously located. The *Washington Public School* is now *Yolo County Offices*.
- The *Chinese Laundry* site is cleared.

1960

- The approach to the I Street Bridge is realigned from D Street to C Street, curving south along 2nd Street.

1968

- A *Boat Repair Shop* is located at the northeast corner of 3rd and C Streets. An unidentified building is located east of the *Plating Works*.

1970

- No significant changes.

Sacramento

EDR provided Sanborn® Maps from 1895, 1915, 1950, 1952, 1957, 1960, 1964, 1965, 1966 and 1968 for the project and surrounding area. Appendix C contains copies of the Sanborn® Maps. This review summary includes the noted changes within and adjacent to the project area as recorded on the maps:

1895

- *Pioneer Mills & Grain Wharf* exists west of First Street adjacent to the Sacramento River.
- First Street parallels the Sacramento River until it juts northeast just north of the Railyard and ends at Sycamore. First Street no longer exists, but appears to be the precursor to present day Jibboom Street.
- A *car repair shop* exists on the east side of First Street across from *Pioneer Mills*.
- Sycamore Street is aligned northwest between the *swamp* and the Sacramento River just north of the Railyard.
- A *coal shed* and *coal pile* associated with the rail yard exists south of Sycamore St.
- Multiple *dwellings* are located along First Street and Sycamore St.
- A *swamp* is identified east of the project area north of the Railyard.

1915

- *Pioneer Mills* is now *Ennis-Brown Co. Warehouse*.
- The portion of First Street that juts northeast is renamed Water Street and connects First Street to Sycamore Street.
- The coal shed and coal piles no longer exist.
- A *scrap iron* pile is located east of Sycamore.
- A *pumping station* is located at the south end of the *Ennis-Brown Warehouse*.
- The *PG&E Power Plant Station B* is identified. *Transformers* are identified on the north side of the building.
- *PG&E wharf* is identified on the Sacramento River west of the power plant.
- *Sacramento Lumber Co*. wharf is identified on the Sacramento River north of the PG&E wharf.

1950, 1952

- Ennis-Brown Co. Warehouse is now identified as *Old Pioneer Warehouse Co. U.S. Government Occupancy.*
- First Street is identified as Jibboom Street viaduct.
- Dwellings along Sycamore are gone and are replaced by *Southern Pacific Store Room and Switch Frog Shop*.

- *PG&E Power Plant Station B* exists in its present location. Three 500,000 gallon above ground fuel oil tanks exist to the east of the power plant building.
- *California Zonolite* (vermiculite insulation) Manufacturing exists west of Jibboom Street north of the Ennis-Brown Warehouse. It is not clear if this site extends into the Jibboom Junkyard site.
- *Sacramento City New Municipal Pumping Station & Filtration Plant* exists east of Jibboom Street. The site consists of a *pumping station*, *filters, settling tanks, clarifiers, aeration fields, misting tanks, coagulation tanks, sedimentation basin* and a *Filtered Water Basin* (Underground).

1957

- A new structure labeled *Open Transfers Switch* is located adjacent to the *Store Room*. A *steel water tank* is located east of Jibboom Street and south of the Store Room.

1960

- East of the PG&E wharf a building labeled "*built in 1913*" identifies contents as *metal storage*/*electric motors*. A structure adjacent to the river, west of Jibboom Street (1st Street) is identified as *Storage*.

1964, 1965

- Three 10,000-gallon Above Ground Tanks are removed from PG&E facility. Two structures identified as *Switchman's Shanty* and *Switch Tender* are located at the east landing from the I Street Bridge.

1966

- The *Store Room* is no longer present.

1968

- No significant changes.

2.6.4 Historical City Directory Review

Historical city directories from the City of West Sacramento and City of Sacramento were reviewed to look for evidence of hazardous materials conditions at or near the project corridor. The City Directory review did not identify any conditions that are not already identified in other sections of this report. The City Directory is provided in Appendix D.

2.6.5 Title Document Review

BCI was not provided title documents for this assessment.

3. RECORDS REVIEW

3.1 County, State and Federal Records Review

BCI requested Environmental Data Resources, Inc. (EDR), a commercial data base search firm, to perform a "Radius Map with GeoCheck" search for the project area on April 16, 2015. The search includes a review of county, state, Federal and EDR proprietary databases for sites located within a 1-mile radius from the approximate outline of the project limits. A copy of the EDR Report, including a complete listing, description and acronyms for the databases searched, is provided in Appendix E. Sites with adequate address information are plotted on EDR's site plan "EDR Radius Map with Geocheck". EDR lists sites with inadequate address information as "orphan sites" and does not provide mapped locations. BCI reviewed the complete list of 15 "orphan sites" identified by EDR and determined that none of these sites appear to be located within or adjacent to the project limits. In addition to the EDR Radius Report, we have obtained data regarding hazardous materials contamination on or near the project limits from the following sources:

- State Water Resources Control Board GeoTracker on-line database
- DTSC EnviroStor on-line database
- Yolo County Environmental Health Services (YCEHS)
- Sacramento County Environmental Health Department (SCEHD)

3.2 Summary of Records Search

The following is a summary of sites within the project corridor or considered close enough to the project corridor to potentially impact the project.

3.2.1 West Sacramento –Acquisition Sites with Known/Potential RECS

The following is a summary of sites located in West Sacramento within the project corridor with known and/or potential RECs.

APN 010-102-005: 205 2nd Street (Historical Brownfield Site), Site A on Figure 2a

Plans indicate proposed improvements of the levy road at the west half of the parcel. This parcel is currently developed as a levy and gravel access road. The site is listed in the US Brownfields and FINDS databases. A Brownfields listing indicates the site is included on the US EPA Assessment, Cleanup and Redevelopment Exchange System (ACRES) online database for Brownfields Grantees to electronically submit data directly to the EPA.

Findings: The site contained a *boat building*, *dwelling unit* and *out buildings* as early as 1915 (Sanborn) until sometime after 1970 when the structures were demolished. Since that time, the site has contained a levy that is part of the Sacramento River levee system. The records search indicates a Phase I ESA was conducted, however, BCI could not locate the report and there were no findings reported in the database search. No specific hazardous material issues were identified in the EDR database search; however, historical site development can be an indication

of potential contamination sources such as leach fields, septic tanks, buried heating oil tanks, and pesticide usage.

APN 010-102-010, APN 010-372-003, APN 010-372-002: (Historical development), Site B on Figure 2a

Plans indicate proposed improvements of the levy road at the west half of these parcels. The parcels are currently developed as a levy and gravel access road. The West Sacramento River Walk water tower, slated for relocation, is located on APN 010-102-010.

Findings: The parcels are not listed in a regulatory database, however, Historical Topographic and Sanborn maps from 1915 and 1950 indicate the presence of *dwellings* and *out buildings*. No specific hazardous material issues are identified; however, historical site development can be an indication of potential contamination sources such as leach fields, septic tanks, buried heating oil tanks, and pesticide usage.

The Washington Firehouse: Sites C and D on Figure 2a

The Washington Firehouse is located at 305 to 317 3rd Street. The site consists of three parcels, two owned by the City of West Sacramento Redevelopment Agency and one owned by the City of Sacramento. Both owners have agreed to develop the parcels as one site. The site(s) is an EPA Brownfields Targeted Site and has been assessed under this program (Ecology and Environment, Inc. Washington Firehouse Brownfields Site Investigation, February 2000). The focus of the report was on the potential impact from the adjacent property, Capitol Plating. Migration of contamination across/beneath the property boundary was suspected because surface water runoff from Capitol Plating drains onto the site and discharges into the storm drain at the Firehouse site. The report concludes that activities at Capitol Plating appear to have impacted soil and groundwater beneath the Washington Firehouse property. Nickel and lead in surface and near surface soils exceed remedial goals, and groundwater at the property boundary is impacted with nickel, cadmium and chromium above their respective maximum contaminant levels (MCL). The parcels are discussed individually below:

- APN 010-371-005 and APN 010-371-006: 305 3rd Street (Old Police Building), Site C on Figure 2a

  Proposed ROW acquisition is planned the north edge of these parcels. The parcels are currently improved with a parking lot and are immediately north of the Washington Firehouse structure. The site is listed in the CA HAZNET database.

  Findings: These parcels were originally developed in 1915 as the Town Hall until 1952 when the site was cleared. In 1957, a new structure was identified on the Sanborn map as the Town Police Station. The site structures were razed sometime after 1993.
- APN 010-371-004: 317 3rd Street (Washington Firehouse, "Lehrer vacant lot"), Site D on Figure 2a

  Project improvements do not appear to impact this parcel. The parcel is improved with an old structure that appeared abandoned at the time of the site inspection. The site is listed in the US Brownfields and FINDS databases.

Findings: The property is a former fire station and police station dating back to the 1940s. A 500-gallon gasoline UST was removed from the property in 1987, however the database listing under Lehrer Vacant Lot indicate two 4,000-gallon gasoline USTs were registered at this site. A UST Permanent closure permit was apparently issued but was not found in our records search.

- APN 010-371-008: 320 2nd Street (Firehouse Block A), Site D on Figure 2a

  Findings: This portion of the Firehouse Block is now vacant with asphalt surfacing and concrete pads remaining in place from prior residential use. The property was initially developed in the late 1890's and early 1900s for residential use. The property is bisected by an overhead freeway access structure which was the reason for removal of the residences. Approximately 0.25 acres of the parcel was used as a parking lot for the adjacent Firehouse property. The site is listed in the US Brownfields and FINDS databases.

Existing Caltrans ROW: C Street (vacant lot), Site Y on Figure 2a

This parcel is not identified in the records search, however it is adjacent to the Washington Firehouse, which has documented soil and groundwater contamination.

Findings: ROW acquisition is proposed for the north edge of the parcel. The parcel is bisected by the overhead freeway access/approach to the I Street Bridge. The parcel is vacant with some scattered trees and shrubs.

APN 010-371-003: 319 3rd Street (Capitol Plating, Stockton Plating), Site E on Figure 2a

A future connection to 2nd Street is identified through the southern and central portion of this parcel. This site is listed in the UST, CA SLIC, HIST UST, CA ENVIROSTOR, CA RESPONSE, EDR Hist Auto Station databases. The site is currently being investigated by the DTSC under the US Brownfields grant program.

Findings: The site is a former metal-plating business, and has no structures on it, other than the remnants of the cinder block retaining wall that was constructed around the plating area. Approximately eighty percent of the site is covered with either concrete or asphalt. The site originally contained one warehouse structure; however, most of the building was destroyed by fire in 1985.

Prior to operation as a plating facility, the parcel reportedly had been developed for residential use (1936-1938) and as a bus/automobile repair facility (1947). The site was operated as an electroplating (chrome-plating) operation under several owners from 1949 until 1985. Stockton Plating, Inc. purchased the assets of Capitol Plating in 1972 and did business as Capitol Plating until plating operations ceased in 1985 when a fire destroyed the storage bay area.

Environmental concerns were identified at the site in May 1986 when elevated concentrations of chromium, copper, nickel, lead and zinc were encountered in soil samples collected from the site. Since then, several field sampling events have been conducted, including the collection of soil samples, groundwater grab samples, and soil gas samples, and the

installation and sampling of five groundwater monitoring wells on site and four monitoring wells off site. Investigation results are found in the Site Summary Investigation (SSI) Report (URS, 2004) located on the EnviroStor website. The SSI determined that soil and groundwater data indicate elevated levels of chromium, nickel and lead in the soil. Impacted soil extends off site to the east and south. Shallow groundwater also is impacted with chromium, hexavalent chromium, nickel, copper and 1, 2-DCA and extends off site (minimally) in all directions but primarily to the south and east. In general, soil within the upper 10 feet contain concentrations above their Preliminary Remediation Goals (PRGs). The maximum planned remediation depth necessary to remove soil above the PRGs is assumed to be at 12 feet bgs. The site is acceptable for current land use, however, during development, further assessment may be required.

APN 010-371-002: 325 3rd Street, Site F on Figure 2a

This parcel is not identified in the records search, however it is adjacent to the historical Capitol Plating site, which has documented soil and groundwater contamination.

Findings: The property is developed with a gravel driveway and one metal shed-type building which was apparently used in conjunction with the adjacent Capitol Plating property. The property is fenced and gated. Project improvements do not appear to impact this parcel.

APN 010-482-011: 301 C Street and 300 3rd Street (Doris Service Station, E&B Auto Sales, Steven's Service, Marsh, Silva Service Station), Site G on Figure 2a

ROW acquisition is proposed for the north edge of the parcel. The parcel is currently vacant and the ground cleared. This site is listed in the EDR US Historical Auto Station database.

Findings: The site is identified as a service station in 1928, 1966, and 1975 in the Historical Auto Station database. The site is also identified as "*gas and oil*" on Sanborn maps from 1950-1970. No additional information was located.

APN 010-101-004: 217/219 3rd Street, Site H on Figure 2a

Plans indicate "possible removal of residence" at this parcel. The site is currently developed as a residence. The site is listed in the EDR Historical Cleaners database.

Findings: The EDR Historical Cleaners database identified a laundry at 223 3rd Street (Sung Lee) in 1923, and Sanborn maps from 1915 identify two laundry facilities at 225 and 217 3rd Street. The 1915 Sanborn map identifies a *washer/dryer* at the 225 3rd Street site. On the 1950 Sanborn map, the *laundry* at 217 has become a *dwelling* and the laundry at 225 is an unidentified structure. The parcel at 225 3rd Street is cleared/undeveloped in 1957.

APN 010-495-014: 424 C Street & 624 5th Street (Martinez Gulf, Parrish Gasoline, Bob's Towing), Site I on Figure 2a

Minor roadway improvements (overlay/resurfacing) are planned for the south edge of the parcel. The parcel is currently developed as what appears to be the original garage structure and parking lot. This site is listed in the EDR US Historical Auto Station and CA HAZNET databases.

Findings: The EDR US Historical Auto Station database identifies the site as a service station in 1966, operating under a variety of names. One 8,000-gallon gasoline, one 10,000-gallon gasoline, one 5,000-gallon gasoline, and one 550-gallon waste oil UST were registered at this site. In 1987, under YCEHS supervision, the four USTs were removed and the inspection report indicated the tanks were tight and there were no odors or visible contamination noted. No additional information was located.

APN 010-481-001: 427 C Street (Gary's Mohawk Service Station, Elmer's Service, and Broderick Auto Service), Site J on Figure 2a

Partial site acquisition is proposed along the north edge of the parcel for minor improvements (overlay/resurfacing). The parcel is currently a vacant lot being used as a community garden. The site is listed in the CA LUST, CA US HIST CORTESE, and HIST UST databases.

Findings: The property was developed as an automobile service station from 1953 until 1990. Three 1,000-gallon gasoline USTs were removed from the facility in August 1990 under YCEHS supervision. Soil samples obtained from beneath the locations of the former tanks contained detectable concentrations of petroleum hydrocarbons. Subsequent excavation of contaminated soil and sampling at the excavation limits in October 1990 indicated the bulk of contaminated soil was removed. Although low concentrations were detected in soil samples obtained from 19 feet bgs, YCEHS authorized backfilling of the former tank pits even after the tank removal firm disclosed historical groundwater levels were shallower than the remaining subsurface soil contaminants. Soil contamination below groundwater levels indicate the possibility that groundwater beneath the subject property may also be impacted.

During tank removal and subsequent excavations, approximately 200 cubic yards of soil was excavated. In 1991, laboratory reports indicate the stockpiled soil was non-hazardous. Based on YCEHS files, it appears that approximately six cubic yards of stockpiled soil was removed off site for disposal. There is no record of how the remaining 194 cubic yards of soil was disposed although records note that it may have been spread onsite.

The City of West Sacramento purchased the property in 1994 and conducted additional soil and groundwater assessments. Soil and groundwater investigations from 1993 through 2010 indicated a potential direct contact risk to residential site use from TPH-mo, cadmium and lead in shallow soil (1-5 feet bgs). The shallow soil contamination is assumed to be due to poor housekeeping issues from the numerous site businesses. Soil was excavated and the excavation backfilled with "clean" backfill material, in order to remove this potential threat to human health. Subsequent sampling indicated the risk to human health had been remediated. Ninyo and Moore (2011), environmental consultants for the City of West Sacramento, reported that groundwater data indicated low concentrations of TPH at one monitoring well, however TPH concentrations

appear to be attenuating under natural conditions, and do not represent a threat to water quality or human health. In July 2012, all four groundwater monitoring wells were destroyed. A NFA letter was issued by RWQCB in August 2012.

APN 010-193-005: 521 C Street and 519 C Street (Golden Eagle Garage), Site K on Figure 2a

Minor improvements are planned for the north east edge of the parcel. The site is partially occupied by a residence and the Golden Eagle Garage building and "decorative" gas pumps. The site is listed in the EDR US Historical Auto Station database and CA UST database.

Findings: The site is identified as a gasoline and oil service station in 1942 and appears in the listing under several names until 1982. The Golden Eagle Garage is identified in the CA UST database. One 750-gallon gasoline, one 500-gallon gasoline, and one 250-gallon gasoline UST were registered at this site. An "Application for Permit to Abandon USTs" was submitted in July 1987 for the removal of the three USTs. The inspection report indicated two steel tanks (one 550-gallon and one 750-gallon) were removed and both USTs were tight and soil clean. The 250-gallon UST is not discussed. The site diagram is not legible due to poor Xerox quality. No closure letter for this facility was located during our review.

APN 101-494-017: 500 C Street (Former Hudson Oil Station, Cole's Shell Service Station, On the Ball Graphics), Site L on Figure 2a

Minor roadway improvements/partial site acquisition is proposed at the southeast corner of the parcel. The site is currently developed as a market and deli and associated parking lot. The site is listed in the CA HIST CORTESE, HIST UST, CA RGA LUST, EDR US Historical Auto Stations and LUST databases.

Findings: This site was developed as a service station since 1966 and has operated under a variety of names. Two 12,000-gallon gasoline, one 8,000-gallon (type unknown), and one 550-gallon waste oil USTs were registered at this site. The USTs were located at the east edge of the parcel. During tank removal in 1987, soil contamination and odors were detected. Laboratory results indicated gasoline range petroleum hydrocarbons and elevated levels of BTEX were present. Upon YCEHS written authorization, the soil was stockpiled, aerated and placed back into the excavation area. A NFA letter was issued in 1987 by YCEHS.

3.2.2 West Sacramento - Adjacent Sites with Known and/or Potential RECS

Roadway improvement plans for this parcel do not indicate any acquisition will occur, however, the site is located adjacent to the project alignment and was reviewed for RECs.

APN 010-560-037: 310 B Street (West Sacramento Lighthouse Pump Station)

It does not appear that improvements will impact this parcel. The parcel is improved with a pump house structure. This site is listed in the UST database.

Findings: One 2,000-gallon diesel UST was registered at this site. The UST was removed in May 2005 by Ramcon Engineering under YCEHS supervision. Soil and groundwater sampling beneath

the tank slab was conducted and were analyzed for diesel, gasoline, BTEX and the five common oxygenates. None of the compounds were detected in either soil samples or groundwater sample above laboratory detection limits. A NFA finding was determined by the county. The records do not indicate suspected soil and/or groundwater contamination.

3.2.3 Sacramento –Acquisition Sites with Known/Potential RECS

The following is a summary of sites located in Sacramento within the project corridor with known and/or potential RECs.

Sacramento Railyards: Figure 2b and 2c

The Sacramento Railyards (Railyards) consist of approximately 240 acres historically developed as a locomotive maintenance and rebuilding facility from the 1860s to the early 1990s. Previous operations at the site resulted in underlying soil and groundwater impacts. In 1988 Southern Pacific Transportation Company (SPTCo) entered into the 1988 Enforceable Agreement with DTSC, which addresses environmental impacts. Union Pacific railroad company (UPRR) entered into a merger with SPTCo in 1996 and acquired the Railyards in 1998. Pursuant to the 1988 Enforceable Agreement, UPRR has investigated and remediated soil and groundwater contamination at the Railyards. In addition, UPRR has certain continuing obligations under the 1988 Enforceable Agreement, including remediation of groundwater, soil vapor, and ongoing operation and maintenance responsibilities. DTSC acts as the lead agency for the cleanup efforts.

The Railyards has been divided into study areas to facilitate investigation and remediation of soil and groundwater. The study areas were identified based on past operations and impacted media. The soil study areas include:

- Lagoon
- Central Shops
- Central Corridor
- Car Shop Nine
- Lagoon Northwest Corner
- Northern Shops
- Sacramento Station

The groundwater study areas include the Lagoon Groundwater (LGWSA) and South Plume (SP). Because of the unique constituents of concern and need for additional investigation of the soil and groundwater conditions, a new study area, Manufactured Gas Plant (MGP) Study Area, was created.

Soil in the Lagoon, Northern Shops, Central Corridor, Car Shop Nine and portions of Sacramento Station have been remediated under their respective RAPS, and certified under DTSC oversight. A LUC was issued in 2015 for these study areas, and DTSC concluded that these areas, as remediated and when used in compliance with the Environmental Restrictions of

the LUC, do not present an unacceptable risk to present and future human health or safety or the environment. The LUC outlines approved land use and provisions for soil, soil vapor and groundwater management.

Provisions of the LUC include, in part:

1. No activities that will disturb the soil shall be allowed on the Property without a soil management plan (SMP) approved in writing by the DTSC
2. Any soil brought to the surface shall be managed in compliance with all applicable provisions of state and federal law and a SMP approved in writing by DTSC
3. No extraction of groundwater except as approved in advance in writing by DTSC in a GMP
4. Vapor intrusion mitigation management is required for enclosed structures or buildings.

Groundwater and soil vapor impacts beneath the property are in the process of being remediated by and are the continuing obligation of UPRR, and contamination in these media will be addressed by the final remedies in the RAPs for the Central Shops soil, South Plume groundwater, future Lagoon Groundwater, and the future MGP soil and groundwater study areas.

Groundwater monitoring wells, groundwater and soil vapor extraction wells, and related groundwater and soil vapor extraction remediation systems (collectively called "Remediation Systems") have been and may continue to be installed as part of remediation in the South Plume and Lagoon Groundwater study areas, and the MGP soil and groundwater study area. Groundwater contamination associated with the South Plume and Lagoon Groundwater has been identified as containing, but not limited to DCA, 1, 2-dichloroethene (DCE), tetrachloroethene (PCE), trichloroethylene (TCE), and vinyl chloride.

The project is located in part, within and/or adjacent to the Northern Shops, MGP and Sacramento Station study areas which are discussed below.

- Northern Shops Study Area (NSA): The new bridge approach is proposed to connect with Railyards Boulevard in the NSA. Site M on Figure 2b

  Findings: Soils in the NSA were investigated and remediated under the RAP for the Northern Shops approved by DTSC in 2000. Additional soil removal for previously inaccessible soil was completed in 2012-2013 when the Mainline Track and Track 150 were removed. During removal of contaminated soil below Track 150, a UST, boilers, pipelines, and bunker fuel were found and removed. Soil contaminated with bunker fuel was excavated to the water table.

  Soil in the NSA is certified and there are no requirements for additional soil investigations, however, all work in this area must comply with the 2015 LUC, Railyards Projects – Soil & Groundwater Management Plan (2015), and property owner approvals and agreements.

Additional characterization and groundwater remediation for this area will be addressed as part of the LGWSA remedy. The 2015 LUC requires that vapor mitigation measures approved by DTSC be implemented for any enclosed structures or buildings.

- Manufactured Gas Plant (MGP) Study Area: The project limits extend through the MGP site boundaries. Site N on Figure 2b and 2c

  Findings: The former MGP area is located in the western portion of the Railyards and includes areas within the Sacramento River levee located between the Railyards and the Sacramento River. The MGP was identified in 2003 during excavation of impacted soil associated with the NSA. A Final RIR was prepared to characterize the occurrence of potentially hazardous substances. Soil, soil vapor and groundwater at the MGP area are impacted. Soil contamination includes metals, TPH, VOCs and SVOCs. Groundwater (in both sand and gravel zones) chemicals of concern include TPH, VOCs, SVOCs and metals. The study also identified VOCs and SVOCs in the soil vapor. This is currently an open case with DTSC as lead agency.

- Sacramento Station Study Area (SSA): The removal and/or demolition of existing bridge approach and viaduct structures are to occur within this study area. Site X on Figure 2c.

  Findings: The Sacramento Station was used as a wheel foundry and depot. The soil was contaminated with metals and TPH. Groundwater contamination includes metals, SVOCs and TPH. The soil remedy for the SSA was selected in 1989. Soil removal was completed in the early 1990s and an LUC was recorded in 1994. The SSA is certified as having its remedy complete. The property is restricted to use as prescribed in the LUC and Railyards Soil and Groundwater Management Plan.

APN 001-0190-017, APN 001-0210-018, and APN 002-0010-023: These parcels are located east of the Sacramento River and West of Jibboom Street. Sites O, P, and Q on Figure 2b

Findings: ROW acquisition is proposed for these three parcels located along the west side of Jibboom Street. The sites are not listed in the searched databases, however, the area has been adjacent to industrial operations at the Railyards and Associated Metals/Jibboom Junk Yard. A portion of the existing levee, although not within the Railyards, was remediated as part of the Railyards clean-up. This area is identified as the "Levee Excavation" (located west of NSA area, adjacent to bike path). In 2008, a small portion of the levee was excavated due to visible impacts (black staining and strong odor) found during excavation of the Lagoon-13 site. Approximately 4,200 cubic yards of soil contaminated with metals and petroleum hydrocarbons were removed from the levee. Confirmation samples were below remedial goals. Remediation of the levee excavation is complete at this location.

APN 006-0011-006 and -009: 111 I Street (CA State Railroad Museum), Site U on Figure 2c

Removal of the existing bridge access structures/ramp is proposed for the area immediately north (adjacent) to and above this parcel. The site is listed in the Sacramento County MLS database. It does not appear that project improvements will impact this parcel.

APN 002-010-027: 904 2nd Street (Historical Cleaners), Site V on Figure 2c

Removal of the existing bridge access structures/ramp is proposed for the area immediately north (adjacent) of this parcel. The site is listed in the Historical Cleaners database in 1923, 1933, 1937, 1942 and 1956. It does not appear that project improvements will impact this parcel.

3.2.4 Sacramento - Adjacent Sites with Known and/or Potential RECS

Roadway improvement plans for these parcels do not indicate any acquisition will occur, however, these sites are located adjacent to the project alignment and were reviewed for RECs.

Sacramento Filtration Plant/City of Sacramento, 101 Bercut Drive, Figure 2b

This site is listed in the following databases: RCRA-SQG, FINDS, HAZNET, CHMIRS, AST, HIST UST, Sacramento Co. ML.

Findings: Two registered USTs, both 750 gallon gasoline tanks were previously located at this site. The site currently maintains one 6,000 gallon above ground fuel storage tank. Contaminated soils from site clean-up, asbestos containing materials and radioactive water waste removal occurred in 2002. Date of completion is not reported.

Associated Metals (Jibboom Street Junkyard), 230-260 Jibboom Street, Site S on Figure 2b

This site is listed in the following databases: CERCLIS, RCRA-SQG, FINDS, CONSENT, Delisted NPL, ROD, US ENG CONTROLS, ENVIROSTOR, HIST Cal-Sites, HAZNET, SLIC, DEED, VCP, and Sacramento Co. ML.

Findings: The site encompasses approximately nine acres although the original size of the site is unknown and may once have covered approximately 35 acres. The nine acre site is the former location of the Associated Metals Company salvage yard. Of the original 9-acre Associated Metals property, approximately 6.7 acres is covered by I-5 and the adjacent, present day Jibboom Street. The remaining 2.3 acres of the former Associated Metals property is a relatively flat open field which has been converted into Jibboom Street Park. Approximately 8-10 feet of clean soil has been added to raise the park to the elevation of the levee.

Hazardous material issues were discovered on this site in 1981. The site was identified as being contaminated with copper, lead, PCBs, and zinc. The Jibboom Junkyard was a National Priority List (NPL) site, but was removed from the database in 1991. Review of the NPL records indicate that the site was closed by the EPA in 1991, due to the fact that all cleanup goals specified by the federal EPA had been met, institutional controls were in place and all required reports and records were completed. Because the site was considered available for unrestricted access and use after completion, a five-year review was not required. However, EPA Region IX elected to complete a discretionary Five-Year Review after the City of Sacramento approved preliminary development plans that could change land-use in the vicinity to residential.

The current alignment of Jibboom Street and I-5 are within the original footprint of the historic Associated Metals Yard. The historic property line of the site extended east under the current alignment of Jibboom Street, I-5 and Bercut Drive. Previous investigation of this site did not extend east under Jibboom Street and beyond. EPA Region IX contends that there is a potential for contamination within the historic junkyard boundaries. In addition, EPA recommends (in the Five Year Review Report for Associated Metals/Jibboom Junkyard) "CalTrans document a management procedure to notify workers that this section of ROW was a Superfund site, with some potential for encountering subsurface contamination". This statement refers to existing Jibboom Street, I-5, and Bercut Drive east of the area formally included in the Associated Metals clean-up which did not investigate or remediate the entire junkyard site.

4. PRIOR ENVIRONMENTAL REPORT REVIEW

BCI reviewed the following reports that were previously prepared for areas that include the project limits. Reports, with the exception of BCI reports, are located on the EnviroStor Database website (http://www.envirostor.dtsc.ca.gov) or via BCI upon request. Our review of these reports support and provide documentation for the findings and discussion presented in this report.

- BCI, "Initial Site Assessment Richards to Railyards Access Improvement Project" dated October 2008
- BCI, "Updated Initial Site Assessment for the I-5/Richards Boulevard Interchange (Ultimate) Project" dated July 2010
- DTSC, "Approval of 2012-2014 Soil Remediation Activities (Mainline Track and Track 150) dated June 2012
- ERM, Final Central Corridor, Car Shop Nine, and Northern Shops Remedial Action Plan for Soil, Former SPTCo Sacramento Railyard, approved February 2000
- ERM, Final Remedial Design and Implementation Plan, 2004, Soil Remediation Activities, Sacramento Railyard, dated July 2004
- ERM, Year 2007-2008 Soil Remediation Summary Report, The Railyards, dated June 2009
- ERM, "2012 Soil Remediation Activities Summary Letter" to DTSC, Northern Shops, Central Corridor, Car Shop Nine, and Lagoon Study Areas, Railyard**s**
- ERM, "2012-2013 Soil Remediation Summary Report for Car Shop Nine, Central Corridor, Lagoon and Northern Shops Study Areas (July 2014)
- ERM, "Remedial Investigation Report –Former Manufactured Gas Plant Study Area" dated April 2015
- DTSC, "Land Use Covenant and Agreement - Environmental Restrictions for Specified Study Areas within the Sacramento Railyards" dated September 2015

5. RECONNAISSANCE, SITE INSPECTION AND OWNER INTERVIEWS

The purpose of a visual survey is to collect evidence of current and/or past use or storage of toxic or hazardous materials, the presence of onsite ponds, landfills, dry wells, waste streams or other disposal units, visible soil contamination, above ground or underground storage tanks, drums, barrels and other storage containers.

BCI conducted a site reconnaissance on December 3, 2014 which included a visual survey of the project area and surrounding sites. A second site reconnaissance was conducted on June 1, 2015. The site reconnaissance was conducted from public roads due to private property access restrictions. On-site inspections of building interiors and other structures, therefore, could not be completed during this visual survey. Consequently, potential RECs such as stained soils, hazardous materials storage areas, enclosed above ground tanks, or underground storage tanks may not have been observed and, therefore, could not be addressed in the scope of this ISA.

Photos from our site visit are included in Appendix F. Our observations generally support the land use descriptions and background data discussed above.

6. OWNER/OPERATOR INTERVIEW

Per ASTM, past owners, operators, and/or occupants of the subject property who are likely to have material information regarding the potential for contamination at the subject property shall be contacted to the extent that they can be identified and that the information likely to be obtained is not duplicative of information already obtained from other sources.

BCI was not provided owner/tenant contact information for the properties located in West Sacramento and, therefore, did not conduct any interviews. BCI considers this data gap a limit to the assessment, but is unlikely to represent a data failure.

BCI conducted an interview with Ruth Cayabyab of the DTSC regarding the current regulatory status of the Railyard. Ms. Cayabyab provided information on the current and upcoming regulatory actions pertaining to the Railyards and specifically the areas impacted by the proposed project. Specifically she stated in an email dated May 29, 2015:

> "The Railyards is a 240-acre site that has been divided into study areas to facilitate investigation and remediation. The study areas were identified based on past operations and impacted media (soil vs groundwater). The study areas include: Sacramento Station, Northern Shops, Central Corridor, Car Shop Nine, Lagoon, Central Shops, Manufactured Gas Plant, South Plume, and Lagoon Groundwater. The place where I Street Bridge is proposed to connect with Railyards Boulevard is in the Northern Shops.
>
> The soil remedy for Sacramento Station was selected in 1989. Soil removal was completed in the early 1990s. A LUC was recorded in 1994, and the study area was certified as having its remedy complete.

The soil remedy for Northern Shops, Central Corridor, Car Shop Nine, and Lagoon was selected in 2000. Soil removal for accessible soil was completed in 2007-2008. Additional soil removal for previously inaccessible soil was completed in 2012-2013 when the Mainline Track and Track 150 were removed. A LUC is planned to be recorded in 2015. The LUC will include a requirement for a soil and groundwater management plan if either media is disturbed, a requirement for clean fill or a cap over "native soil" (soil cleaned up to the remedial goals), and a requirement for soil vapor mitigation measures.
The soil remedy for Central Shops was selected in 2013. Soil removal is being implemented in 2015. The soil remedy for Manufactured Gas Plant has not yet occurred. The groundwater remedies for South Plume and Lagoon Groundwater are ongoing.

As stated before, the place where I Street Bridge is proposed to connect with Railyards Boulevard is in the Northern Shops. Most of the soil cleanup in Northern Shops was finished in 2007-2008. Soils that were below Track 150 were removed in 2012-2013. During removal of contaminated soil below Track 150, an underground storage tank (UST), boilers, pipelines, and bunker fuel were found and removed. Soil contaminated with bunker fuel was excavated to the water table. Some areas of impacted soil remain but are outside the area of the future bridge. A LUC is planned to be recorded in 2015."

7. FINDINGS AND CONCLUSIONS

This Initial Site Assessment's objective is to:

- Determine whether there may be hazardous materials at or near the project limits at concentrations likely to warrant mitigation pursuant to regulations;
- Identify recognized environmental conditions (RECs) and/or potential RECs at or near the project limits which could affect property acquisition;
- Identify potential site contamination issues.

This assessment identified the following RECs and/or potential RECs that should be considered in planning for improvements.

7.1 West Sacramento –Partial Acquisition Parcels with Known/Potential RECs

The following is a summary of sites located in West Sacramento within the project corridor with known and/or potential RECs.

APN 010-102-005: 205 2nd Street, Site A on Figure 2a

Plans indicate proposed improvements of the levy road at the west half of the parcel. This parcel is currently developed as a levy and gravel access road.

Findings: The site was developed with a variety of structures as early as 1915 (Sanborn) until sometime after 1970 when the structures were demolished. No specific hazardous material issues were identified in the EDR database search; however, historical site development can be

an indication of potential contamination sources such as leach fields, septic tanks, and buried heating oil tanks.

Conclusions: *Although none of the potential RECs were positively identified in this ISA, plans for construction and/or partial acquisition should account for the potential to encounter a leach field, septic tank and/or buried heating oil tanks.*

APN 010-102-010, APN 010-372-003, APN 010-372-002: (Historical development), Site B on Figure 2a

Plans indicate proposed improvements of the levy road at the west half of these parcels and the relocation of the Sacramento River Walk water tower. The parcels are currently developed with the water tower, levy and gravel access road.

Findings: The site was developed with a variety of structures as early as 1915 until sometime after 1970 when the structures were demolished. The Sacramento River Walk water tower is the only remaining structure. No specific hazardous material issues are identified but historical site development can be an indication of potential contamination sources such as leach fields, septic tanks, buried heating oil tanks, and pesticide usage.

Conclusions: *Although none of the potential RECs were positively identified in this ISA, plans for construction and/or partial acquisition should account for the potential to encounter a leach field, septic tank and/or buried heating oil tanks.*

The Washington Firehouse: Sites C and D of Figure 2a

ROW acquisition is proposed for the north edges of Sites C.

The Washington Firehouse sites are an EPA Brownfields Targeted Site and have been assessed under this program. The focus of the report was on the potential impact from the adjacent property, Capitol Plating. Migration of contamination across/beneath the property boundary was suspected because surface water runoff from Capitol Plating drains onto the site and discharges into the storm drain at the site. The report concludes that activities at Capitol Plating appear to have impacted soil and groundwater beneath the Washington Firehouse property. The parcels are discussed individually below:

- APN 010-371-005 and APN 010-371-006: 305 3rd Street (Old Police Building), Site C on Figure 2a, ROW acquisition is proposed for the north edges of the parcels.

  Findings: Known soil and ground water contamination exist at this property. Soil and ground water assessments were completed for the parcel, however the sampling locations were not within the proposed ROW acquisition/improvement area for this project.

  Conclusion: BCI recommends a Phase II assessment within the proposed acquisition area be completed.

- APN 010-371-004: 317 3rd Street (Washington Firehouse, Lehrer vacant lot), Site D on Figure 2a

Findings: The property is a former fire station and police station dating back to the 1940s. A 500-gallon gasoline UST was removed from the property in 1987, however the database listing under a second name "Lehrer Vacant Lot" indicate two 4,000-gallon gasoline USTs were registered at this site.

Conclusion: *BCI understands that improvements at this parcel may not occur as part of this project, however, if project plans change and any construction or site acquisition is planned at this parcel, we recommend further assessment. The additional assessment will include a detailed review of existing environmental records at YCEHS and RWQCB to determine current status of compliance; if additional information is not available, conduct a Phase II assessment within the proposed acquisition area*.

- APN 010-371-008: 320 2nd Street (Firehouse Block), Site D (southeast) on Figure 2a

  Findings: Potential migration of contamination across/beneath the property boundary from Capitol Plating.

  Conclusion: *BCI understands that improvements at this parcel may not occur as part of this project, however, if project plans change and any construction or site acquisition is planned at this parcel, we recommend further assessment. The additional assessment will include a detailed review of existing environmental records at YCEHS and RWQCB to determine current status of compliance; if additional information is not available, conduct a Phase II assessment within the proposed acquisition area.*

Parcel APN 010-371-003: 319 3rd Street (Capitol Plating), Site E on Figure 2a

The Washington Specific Plan identifies a future connection to 2nd Street through the southern and central portion of this parcel.

Findings: Soil is impacted with elevated levels of chromium, nickel and lead. Impacted soil extends off site to the east and south. Shallow groundwater is impacted with chromium, hexavalent chromium, nickel, copper and 1, 2-DCA and extends off site (minimally) in all directions but primarily to the south and east.

Conclusions: *BCI understands that improvements at this parcel may not occur as part of this project, however, if project plans change and any construction or site acquisition is planned at this parcel, we recommend further assessment. The additional assessment will include a detailed review of existing environmental records at YCEHS and the RWQCB to determine current status of compliance; if additional information is not available, conduct a Phase II assessment within the proposed acquisition area.*

Parcel APN 010-371-002: 325 3rd Street, Site F on Figure 2a

This parcel is identified for a future connection as identified in the Washington Specific Plan.

Findings: Potential migration of contamination across/beneath the property boundary from Capitol Plating.

Conclusion: *BCI understands that improvements at this parcel may not occur as part of this project, however, if project plans change and any construction or site acquisition is planned at this*

parcel, we recommend further assessment. The additional assessment will include a detailed review of existing environmental records at YCEHS and RWQCB to determine current status of compliance; if additional information is not available, conduct a Phase II assessment within the proposed acquisition area.

APN 010-482-011: 301 C Street and 300 3rd Street (E&B Auto Sales, Steven's Service, Marsh, Dorris Service Station, Silva Service Station), Site G on Figure 2a

ROW acquisition is proposed for the north edges of the parcel.

Findings: The site is identified as a service station in 1928, 1966, and 1975 in the Historical Auto Station database. The site is also identified as "*gas and oil*" on Sanborn maps from 1950-1970. No additional information was located.

Conclusions: *Due to the limited information available for this site, we recommend a detailed review of existing environmental records at YCEHS and the RWQCB and an owner/tenant interview to determine current status of compliance. If no additional information is available, conduct a Phase II assessment within the proposed acquisition area.*

APN 010-101-004: 217/219 3rd Street, Site H on Figure 2a

Plans indicate "possible removal of residence" at this parcel. The site is currently developed as a residence.

Findings: The EDR Historical Cleaners database identifies a laundry at 223 3rd Street (Sung Lee) in 1923 and Sanborn maps from 1915 identify two *laundry* facilities (at 225 and 217 3rd Street). The 1915 Sanborn map identifies a *washer/dryer* at the 225 3rd Street site. Prior to the 1930s, smaller laundry facilities typically collected garments and sent them to centralized cleaning facilities for treatment/cleaning, due to the high risk of fire from the cleaning solvents utilized before perchloroethylene; however, the presence of the washer/dryer indicate cleaning solvents may have been used on this site. On the 1950 Sanborn map, the *laundry* at 217 has become a dwelling and the *laundry* at 225 is an unidentified structure. The parcel at 225 3rd Street is cleared/undeveloped in 1957 and is not developed until 2002.

Conclusions: *Neither address listed on the Sanborn maps correspond with the database listing, however, the laundry at 217 3rd Street appears to be where the possible removal of the residence is proposed. The laundry at 217 3rd Street did not appear to have a washer/dryer associated with the site. Due to the limited information available for this site, we recommend an owner/tenant interview to determine site history. If additional information is not available, a Phase II assessment may be needed.*

Existing Caltrans ROW: C Street (vacant lot), Site Y on Figure 2a

This parcel is not identified in the records search, however it is adjacent to the Washington Firehouse, which has documented soil and groundwater contamination.

Findings: ROW acquisition is proposed for the north edge of the parcel. Removal of the existing bridge approach at this parcel is to occur.

Conclusion: *Conduct a Phase II assessment for metals within the depth of construction impacts. Metals may potentially originate from historical Capitol Plating operations and/or on-going ADL impacts.*

7.2 West Sacramento - Adjacent Sites with Known and/or Potential RECs

Roadway improvement plans for these parcels do not indicate any acquisition will occur, however, these sites are located adjacent to the project alignment and were reviewed for RECs.

Parcel APN 010-495-014: 424 C Street (624 5th Street) (Martinez Gulf Service, Parrish Gasoline), Site I on Figure 2a

Minor roadway improvements (overlay/resurfacing) are planned for the area adjacent to the south edge of the parcel. The parcel is currently developed as what appears to be the original garage structures and parking lot.

Findings: Four USTs were removed and the inspection report indicated the tanks were tight and there were no odors or visible contamination noted.

Conclusions: *BCI understands that improvements adjacent to this parcel will include only overlay and resurfacing, and no portion of the parcel will be acquired. Based on our records review, site observations, and the location of the former USTs, we don't expect residual, shallow soil or groundwater contamination in the planned construction zone; however, if more extensive construction or site acquisition is planned, we recommend a detailed review of existing environmental records at YCEHS and the RWQCB, a site inspection and an owner/tenant interview to determine current status of compliance. If additional information is not available, a Phase II subsurface investigation may be needed.*

Parcel APN 010-481-001: 427 C Street (Gary's Mohawk Service Station, Elmer's Service, and Broderick Auto Service), Site J on Figure 2a

Minor roadway improvements (overlay/resurfacing) are planned for area adjacent to the north edge of the parcel. The parcel is currently a vacant lot being used as a garden.

Findings: The property was developed as an automobile service station from 1953 until 1990. Three USTs were removed from the facility in August 1990 under YCEHS supervision. Soil samples obtained from beneath the locations of the former tanks contained detectable concentrations of petroleum hydrocarbons. Subsequent excavation of contaminated soil and sampling at the excavation limits in October 1990 indicated the bulk of contaminated soil was removed.

The City of West Sacramento purchased the property in 1994 and conducted additional soil and groundwater assessments. Soil and groundwater investigations from 1993 through 2010 indicated soils were impacted by TPH-mo, cadmium and lead in shallow soil (1-5 feet bgs). Soil was excavated and the excavation backfilled with "clean" backfill material. Subsequent sampling indicated the risk to human health had been remediated. Groundwater data indicated low concentrations of TPH at one monitoring well. TPH concentrations appear to be attenuating

under natural conditions, and do not represent a threat to water quality or human health. In July 2012, all four groundwater monitoring wells were destroyed. A NFA letter was issued by the RWQCB in August 2012.

Conclusions: *BCI understands that improvements adjacent to this parcel will be surficial, including only overlay and resurfacing, and no portion of the parcel will be acquired. For the planned construction conditions, we do not anticipate the need for a further assessment*.

APN 010-193-005: 521 C Street and 519 C Street (Golden Eagle Garage, Parkinson), Site K on Figure 2a

Minor improvements (overlay and surfacing) are planned for the area adjacent to the northeast edge of the parcel. The site is partially occupied by a residence and the Golden Eagle Garage building and "decorative" gas pumps.

Findings: One 750-gallon gasoline, one 500-gallon gasoline, and one 250-gallon gasoline UST were registered at this site. An application for Permit to Abandon USTs was submitted in July 1987 for the removal of the three USTs. The YCEHS inspection report indicated two steel tanks (one 550-gallon and one 750-gallon) were removed and both USTs were "tight and soil clean". The 250-gallon UST is not discussed. The site diagram is not legible due to poor Xerox quality. No closure letter for this facility was encountered during our review.

Conclusions: *BCI understands that improvements adjacent to this parcel will be surficial (i.e. no more than 2 feet below the existing ground surface), and no portion of the parcel will be acquired. For the planned construction conditions, we do not anticipate the need for further assessment. If project plans change and ROW acquisition or project improvements include this parcel, conduct a Phase II assessment within the proposed acquisition/improvement area*.

Parcel APN 101-494-017: 500 C Street (Former Hudson Oil Station, Cole's Shell Service Station, On the Ball Graphics), Site L on Figure 2a

Minor roadway improvements/partial site acquisition is proposed at the southeast corner of the parcel. The site is currently developed as a market and deli and associated parking lot.

Findings: This site was developed as a service station since 1966 and has operated under a variety of names including Hudson Oil, Cole's Shell and On the Ball Graphics. Two 12,000-gallon gasoline, one 8,000-gallon (unknown), and one 550-gallon waste oil USTs were registered at this site. The USTs were located at the east edge of the parcel. During tank removal in 1987, soil contamination and odors were detected. Laboratory results indicated gasoline range petroleum hydrocarbons and elevated levels of BTEX were present. Upon YCEHS written authorization, the soil was stockpiled, aerated and placed back into the excavation area. A NFA letter was issued in 1987 by YCEHS.

Conclusion: *BCI understands that improvements adjacent to this parcel will be surficial (i.e. no more than 2 feet below the existing ground surface) and no portion of the parcel will be acquired. For the planned construction conditions we do not anticipate the need for a further assessment. If project plans change and ROW acquisition or project improvements include this parcel, conduct a Phase II assessment within the proposed acquisition/improvement area*.

7.3 Sacramento – Partial Acquisition Parcels with Known/Potential RECs

The following is a summary of sites located in Sacramento within the project corridor with known and/or potential RECs.

Sacramento Railyards

Previous operations at the site resulted in underlying soil and ground water impacts. In 1988 SPTCo entered into the 1988 Enforceable Agreement addressing environmental impacts. UPRR entered into a merger with SPTCo in 1996 and acquired the Railyards in 1998. Pursuant to the 1988 Enforceable Agreement, UPRR has investigated and remediated soil and groundwater contamination at the Railyards. In addition, UPRR has certain continuing obligations under the 1988 Enforceable Agreement, including remediation of groundwater, soil vapor, and ongoing operation and maintenance responsibilities. DTSC acts as the lead agency for the cleanup efforts.

The Railyards has been divided into study areas to facilitate investigation and remediation of soil and groundwater. The study areas were identified based on past operations and impacted media. The soil study areas include the Lagoon, Central Shops, Central Corridor, Car Shop Nine, Lagoon Northwest Corner, Northern Shops, and Sacramento Station. The groundwater study areas include the LGWSA and SP. Because of the unique constituents of concern and need for additional investigation, a new study area was created for the soil and groundwater conditions in the MGP Study Area.

Soil in the Lagoon, Northern Shops, Central Corridor, Car Shop Nine and portions of Sacramento Station have been remediated under their respective RAPS, and certified under DTSC oversight. A LUC was issued in 2015 for these study areas, and DTSC has concluded that these areas, as remediated and when used in compliance with the Environmental Restrictions of the LUC, do not present an unacceptable risk to present and future human health or safety or the environment. The LUC outlines provisions for soil, soil vapor and groundwater management.

Groundwater and soil vapor impacts beneath the property are in the process of being remediated by and are the continuing obligation of UPRR, and contamination in these media will be addressed by the final remedies of the Central Shops soil and SP RAP and the future LGWSA RAP and the future MGP soil and groundwater study area RAP.

Groundwater monitoring wells, groundwater and soil vapor extraction wells, and related groundwater and soil vapor extraction remediation systems (collectively called “Remediation Systems”) have been and may continue to be installed as part of remediation in the South Plume and Lagoon Groundwater study areas and the MGP soil and groundwater study areas.

The project is located within and/or adjacent to the Northern Shops, Sacramento Station, and Manufactured Gas Plant study areas which are discussed below.

- Northern Shops: The new bridge approach is proposed to connect with Railyards Boulevard in the NSA. Site M on Figure 2b

  Findings: Soils in the NSA were investigated and remediated under the Remediation Action Plan (RAP) for the Northern Shops approved by DTSC in 2000. Soil in the NSA is certified and there are no requirements for additional soil investigations. Additional characterization and groundwater remediation for this area will be addressed as part of the Lagoon Groundwater Study Area remedy.

  Conclusions: *All work must comply with the 2015 LUC, Railyards Projects – Soil & Groundwater Management Plan (2015); and property owner approvals and agreements. Groundwater impacts have not been established by UPRR, therefore a Phase II assessment of groundwater to depth of construction is recommended. All Phase II sampling plans must be approved by DTSC.*

- Manufactured Gas Plant: The project limits extend through the MGP study area boundaries. Site N on Figure 2b and 2c

  Findings: A Final RIR was prepared to characterize the occurrence of potentially hazardous substances. Soil, soil vapor and groundwater at the MGP area are impacted. Soil contamination includes metals, TPH, VOCs and SVOCs. Groundwater (in both sand and gravel zones) chemicals of concern include TPH, VOCs, SVOCs and metals. Project improvements are limited to removal of existing Jibboom Street viaduct.

  Conclusions: If soil remedy is complete and soils are certified prior to construction, comply with resulting LUC and/or guidance documents. If site characterization is not complete, conduct Phase II assessment within the depth and area of construction improvements.

- SSA: The removal and/or demolition of existing bridge approach and viaduct structures are to occur within this study area. Site X on Figure 2c.

  Findings: The soil remedy for the SSA was selected in 1989 and soil removal was completed in the early 1990s. A LUC was recorded in 1994.

  Conclusions: *All work must comply with the 1994 LUC, Railyards Projects – Soil & Groundwater Management Plan (2015); and property owner approvals and agreements.*

APN 001-0190-017, APN 001-0210-018, and APN 002-0010-023: These parcels are located east of the Sacramento River and West of Jibboom Street. Sites O, P, and Q on Figure 2b

Findings: ROW acquisition is proposed for these three parcels. The sites are not listed in the searched databases, however, the area has been adjacent to industrial operations at the Railyards and Associated Metals/Jibboom Junk Yard. A portion of the existing levee, although not within the Railyards, was remediated as part of the Railyards clean-up. This area is called the Levee Excavation (located at the west edge of Northern Shop area, adjacent to bike path). In 2008, a small portion of the levee was excavated due to visible impacts (black staining and strong odor) found during excavation of the Lagoon-13 site. Approximately 4200 cubic yards was removed

from the levee. Confirmation samples were below remedial goals. Remediation of the levee excavation is complete.

Conclusion: *Complete a Phase II subsurface investigation to evaluate the potential for metals, TPH and PCB impacts for all construction activities that will result in soil excavation within the proposed ROW adjacent to Jibboom Street at these parcels. Based on the findings of the Phase II investigation, a soils management plan and health and safety plan may be necessary*

APN 002-010-027: 111 I Street (CA State Railroad Museum), Site U on Figure 2c

Findings: Removal of former bridge access structures/ramp is proposed for the area immediately north (adjacent) of this parcel. The site is listed in the Sacramento County MLS database. It does not appear that this parcel will impact the project.

Conclusion: *No further assessment*.

APN 002-010-027: 904 2nd Street (Historical Cleaners), Site V on Figure 2c

Removal of former bridge access structures/ramp is proposed for the area immediately north (adjacent) of this parcel. The site is listed in the Historical Cleaners database in 1923, 1933, 1937, 1942 and 1956. It does not appear that this parcel will impact the project.

Conclusion: No further assessment.

7.4 Sacramento – Adjacent Sites with Known/Potential RECs

Roadway improvement plans for these parcels do not indicate any acquisition will occur, however, these sites are located adjacent to the project alignment and were reviewed for RECs.

Sacramento Filtration Plant/City of Sacramento, 101 Bercut Drive, Site R on Figure 2b

Findings: Two registered USTs, both 750 gallon gasoline tanks were previously located at this site. The site currently maintains one 6,000 gallon above ground fuel storage tank. Contaminated soils from site clean-up, ACM and radioactive water waste removal occurred in 2002.

Conclusion: *Based on our records review, site observations, and the location of the former USTs, we don't expect residual contamination in the planned construction zone. If more extensive construction or site acquisition is planned, a Phase II assessment may be needed. No additional assessment.*

Associated Metals/Jibboom Street Junkyard**,** 230-260 Jibboom Street, Site S on Figure 2b

Findings: The site encompasses approximately nine acres although the original size of the site is unknown and may once have covered approximately 35 acres. Of the original nine acre Associated Metals property, approximately 6.7 acres is covered by I-5 and the adjacent, present day Jibboom Street. The remaining 2.3 acres of the former Associated

Metals property has been converted into Jibboom Street Park. Approximately 8-10 feet of clean soil has been added to raise the park to the elevation of the levee.

The current alignment of Jibboom Street and I-5 are within the original footprint of the historic Associated Metals Yard. The historic property line of the site extends east under the current alignment of Jibboom Street, I-5 and Bercut Drive. Previous investigation of this site did not extend east under Jibboom Street and beyond. Region IX, USEPA contends that there is a potential for contamination within the historic junkyard boundaries. In addition, EPA recommends (Five Year Review Report for Jibboom Junkyard) "Caltrans document a management procedure to notify workers that this section of ROW was a superfund site, with some potential for encountering subsurface contamination". This statement refers to existing Jibboom Street, I-5, and Bercut Drive east of the area formally included in the Jibboom Street Junkyard clean-up which did not investigate or remediate the entire junkyard site.

Conclusion: *Complete a Phase II assessment to evaluate the potential for metals and PCB impacts for all construction activities that will result in soil excavation within the extent of the former Jibboom Junkyard property. Based on the findings of the Phase II investigation, a soils management plan and health and safety plan may be necessary.*

7.5 General Contamination Issues

Asbestos Containing Materials (ACM) and Lead Based Paint (LBP)

The USEPA NESHAP, 40 CFR Part 61 – Nov 20, 1990, requires an owner or operator of a demolition or renovation project to thoroughly inspect the affected facility or part of the facility where the demolition or renovation operation will occur for the presence of ACM prior to the commencement of that project.

Findings: The I Street Bridge and its associated approaches are proposed for demolition or modification. BCI had the bridge and approaches surveyed for ACM and LCP by Entek, a California Certified Asbestos Consultant and certified Lead Inspector/Assessor. Findings of the surveys are summarized below and the complete Hazardous Materials Survey Final Report (dated 14 May 2015) is in Attachment 1. The report concluded that ACM is present in the railing gaskets and the fastener sealants. Specifics pertaining to individual materials are presented in the attached report.

Entek also investigated existing paints and applied coatings associated with the bridge to determine if lead was present in these materials. Three paints/locations were determined to have paint containing more than 5,000 ppm lead and are classified as lead-based paint: silver paint on metal bridge structure, black paint on metal bridge structure and white paint on metal northeast approach. In addition, the gasket located at the base of the light boxes on the northeast approaches was determined to be pure lead. Precaution should be used when handling this material.

Conclusion: Any demolition or modification of the bridge and/or approach structures within the project area will require that an appropriate ACM and Lead Compliance Plan be developed.

Abatement of LCP and/or ACM shall be conducted, as necessary, by contractors certified to perform such work in accordance with state and federal regulations.

ACM/LCP in Buildings/Residences

The ACM/LCP assessment did not include buildings within the project limits. Typically pre-demolition surveys for occupied buildings are conducted at a later date. Any structure constructed pre-1980 has the potential to contain ACM/LCP materials

Recommendation: *Any structure identified for modification and/or demolition that was constructed pre-1980, must be surveyed by a certified Asbestos Inspector prior to building demolition/modification.*

Aerially Deposited Lead

ADL has been found to occur in soils adjacent to highways and high use roadways. The lead is presumably from the historical use of leaded gasoline and subsequent exhaust emissions. There is potential for encountering ADL during construction and grading activities within the proposed project limits in West Sacramento along C Street, 2nd Street and at the bridge approach/viaduct leading from C Street. A majority of the area adjacent to C Street is covered sidewalk; therefore, an ADL assessment would be limited to areas with exposed soils in that area.

There is potential for encountering ADL during construction and grading activities within the proposed project limits in Sacramento at the bridge approach/viaduct leading from I Street, and along Jibboom Street and Bercut Drive, which have been present in various alignments since 1916 and, therefore, have the potential to be impacted with ADL. BCI conducted an ADL Assessment in 2009 for portions of Jibboom Street north of the current project limits. The 2009 Assessment results indicate that soils from the tested area would be classified as either non-hazardous or as soil acceptable for management in accordance with DTSC and the RWQCB.

In addition, the bridge landing will be located within the Sacramento Railyards. This area is not likely to exhibit elevated concentrations of ADL from typical automobile emissions; however, historical operations at the Railyards has impacted the site with metals including lead. Approved total lead concentrations for soils within the railyards will be guided by the Remediation Goals set for each study area by DTSC.

Recommendation: *Conduct an ADL study within the project limits along C Street, 2nd Street and adjacent to and below the bridge approach/viaduct in West Sacramento; and along Jibboom Street, the new extension of Bercut Drive, and adjacent to and below the bridge approach/viaduct in Sacramento. Within the Railyards property, conduct all operations in compliance with the LUC of 2015, and Railyards Soil and Groundwater Management Plan.*

8. QUALIFICATIONS

Laura Long with BCI prepared this ISA. I declare that, to the best of my professional knowledge and belief, I meet the definition of an environmental professional as defined in Section 312.10 of 40 Code of Federal Regulations (CFR) 312 and have the specific qualifications based on education, training, and experience to assess a property of its nature, history, and setting of the subject property. I have performed all appropriate inquiries in general conformance with the standards and practice set forth in 40 CFR 312.

9. LIMITATIONS

The accompanying report summarizes the findings and opinions of BCI, with regard to the potential for hazardous materials to be present on the properties at concentrations likely to warrant mitigation under current statutes and guidelines. Our findings and opinions are based on information obtained on given dates or provided by specified individuals, through records review, site review, and related activities. Our information is only as good as the information provided to us. Conditions can change after we have made our observations. We cannot warrant or guarantee that hazardous materials do not exist at the described site. To further reduce your risk, invasive exploration may be necessary.

This report was prepared for the specific use of our client and applies only to the subject area. We are not responsible for interpretations by others of data presented in this report.

This report does not represent a legal opinion. No warranty is expressed or implied. We base our conclusions in this report on judgment and experience. We performed this work in accordance with generally accepted standards of practice existing in northern California at the time of the assessment.

The scope of our investigation did not include a determination of the presence of radon. We did not determine the presence of lead-based paint or asbestos-containing materials at all building/structure locations. Identification of endangered species, geologic hazards, or archeological sites are also beyond the scope of this report.

The project involves land and land use with restrictions and prior agreements. The property owner/user should thoroughly review all land use restrictions and requirements and understand the implications to the proposed project improvements.

The governmental records portion of this report is derived from public records and is updated on a continual basis. For this reason, we do not advise you to use this information to base a decision after 180 days of the issue date of this report. Also, conditions at the site can and will change over time. Please contact BCI to revise this report to reflect new information.

EDR Aerial Photo Decade Package

Environmental Data Resources, Inc. (EDR) Aerial Photo Decade Package is a screening tool designed to assist environmental professionals in evaluating potential liability on a target property resulting from past activities. EDR's professional researchers provide digitally reproduced historical aerial photographs, and when available, provide one photo per decade.

When delivered electronically by EDR, the aerial photo images included with this report are for ONE TIME USE ONLY. Further reproduction of these aerial photo images is prohibited without permission from EDR. For more information contact your EDR Account Executive.

Thank you for your business.
Please contact EDR at 1-800-352-0050
with any questions or comments.

EDR Inquiry # 3893331.3

Contact: Laura Long

The Sanborn Library has been searched by EDR and maps covering the target property location as provided by Blackburn Consulting were identified for the years listed below. The Sanborn Library is the largest, most complete collection of fire insurance maps. The collection includes maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow, and others. Only Environmental Data Resources Inc. (EDR) is authorized to grant rights for commercial reproduction of maps by the Sanborn Library LLC, the copyright holder for the collection. Results can be authenticated by visiting www.edrnet.com/sanborn.

The Sanborn Library is continually enhanced with newly identified map archives. This report accesses all maps in the collection as of the day this report was generated.

Sanborn® Library search results
Certification # 5524-423E-B51B

The Sanborn Library includes more than 1.2 million fire insurance maps from Sanborn, Bromley, Perris & Browne, Hopkins, Barlow and others which track historical property usage in approximately 12,000 American cities and towns. Collections searched:

- ☑ Library of Congress
- ☑ University Publications of America
- ☑ EDR Private Collection

The Sanborn Library LLC Since 1866™

Limited Permission To Make Copies

Blackburn Consulting (the client) is permitted to make up to FIVE photocopies of this Sanborn Map transmittal and each fire insurance map accompanying this report solely for the limited use of its customer. No one other than the client is authorized to make copies. Upon request made directly to an EDR Account Executive, the client may be permitted to make a limited number of additional photocopies. This permission is conditioned upon compliance by the client, its customer and their agents with EDR's copyright policy; a copy of which is available upon request.

EXECUTIVE SUMMARY

DESCRIPTION

Environmental Data Resources, Inc.'s (EDR) City Directory Abstract is a screening tool designed to assist environmental professionals in evaluating potential liability on a target property resulting from past activities. EDR's City Directory Abstract includes a search and abstract of available city directory data. For each address, the directory lists the name of the corresponding occupant at five year intervals.

Business directories including city, cross reference and telephone directories were reviewed, if available, at approximately five year intervals for the years spanning 1920 through 2013. This report compiles information gathered in this review by geocoding the latitude and longitude of properties identified and gathering information about properties within 660 feet of the target property.

A summary of the information obtained is provided in the text of this report.

RESEARCH SUMMARY

The following research sources were consulted in the preparation of this report. An "X" indicates where information was identified in the source and provided in this report.

EXECUTIVE SUMMARY

A search of available environmental records was conducted by Environmental Data Resources, Inc (EDR). The report was designed to assist parties seeking to meet the search requirements of EPA's Standards and Practices for All Appropriate Inquiries (40 CFR Part 312), the ASTM Standard Practice for Environmental Site Assessments (E 1527-13) or custom requirements developed for the evaluation of environmental risk associated with a parcel of real estate.

EXECUTIVE SUMMARY

EDR RECOVERED GOVERNMENT ARCHIVES

Exclusive Recovered Govt. Archives

CA RGA LF..... Recovered Government Archive Solid Waste Facilities List

SURROUNDING SITES: SEARCH RESULTS

Surrounding sites were identified in the following databases.

Elevations have been determined from the USGS Digital Elevation Model and should be evaluated on a relative (not an absolute) basis. Relative elevation information between sites of close proximity should be field verified. Sites with an elevation equal to or higher than the target property have been differentiated below from sites with an elevation lower than the target property.
Page numbers and map identification numbers refer to the EDR Radius Map report where detailed data on individual sites can be reviewed.

Sites listed in ***bold italics*** are in multiple databases.

Unmappable (orphan) sites are not considered in the foregoing analysis.

STANDARD ENVIRONMENTAL RECORDS

Federal Delisted NPL site list

Delisted NPL: The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) establishes the criteria that the EPA uses to delete sites from the NPL. In accordance with 40 CFR 300.425.(e), sites may deleted from the NPL where no further response is appropriate.

A review of the Delisted NPL list, as provided by EDR, and dated 12/16/2014 has revealed that there is 1 Delisted NPL site within approximately 1 mile of the target property.

JIBBOOM JUNKYARD	***240 - 260 JIBBOOM ST***	***N 1/4 - 1/2 (0.261 mi.)***	***AG230***	***430***

Federal CERCLIS list

CERCLIS: The Comprehensive Environmental Response, Compensation and Liability Information System contains data on potentially hazardous waste sites that have been reported to the USEPA by states, municipalities, private companies and private persons, pursuant to Section 103 of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA). CERCLIS contains sites which are either proposed to or on the National Priorities List (NPL) and sites which are in the screening and assessment phase for possible inclusion on the NPL.

A review of the CERCLIS list, as provided by EDR, and dated 10/25/2013 has revealed that there are 2 CERCLIS sites within approximately 0.5 miles of the target property.

EXECUTIVE SUMMARY

Federal CERCLIS NFRAP site List

CERC-NFRAP: Archived sites are sites that have been removed and archived from the inventory of CERCLIS sites. Archived status indicates that, to the best of EPA's knowledge, assessment at a site has been completed and that EPA has determined no further steps will be taken to list this site on the National Priorities List (NPL), unless information indicates this decision was not appropriate or other considerations require a recommendation for listing at a later time. This decision does not necessarily mean that there is no hazard associated with a given site; it only means that, based upon available information, the location is not judged to be a potential NPL site.

A review of the CERC-NFRAP list, as provided by EDR, and dated 10/25/2013 has revealed that there is 1 CERC-NFRAP site within approximately 0.5 miles of the target property.

Federal RCRA CORRACTS facilities list

CORRACTS: CORRACTS is a list of handlers with RCRA Corrective Action Activity. This report shows which nationally-defined corrective action core events have occurred for every handler that has had corrective action activity.

A review of the CORRACTS list, as provided by EDR, and dated 12/09/2014 has revealed that there is 1 CORRACTS site within approximately 1 mile of the target property.

Federal RCRA non-CORRACTS TSD facilities list

RCRA-TSDF: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Transporters are individuals or entities that move hazardous waste from the generator offsite to a facility that can recycle, treat, store, or dispose of the waste. TSDFs treat, store, or dispose of the waste.

A review of the RCRA-TSDF list, as provided by EDR, and dated 12/09/2014 has revealed that there is 1 RCRA-TSDF site within approximately 0.5 miles of the target property.

EXECUTIVE SUMMARY

Federal RCRA generators list

RCRA-LQG: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Large quantity generators (LQGs) generate over 1,000 kilograms (kg) of hazardous waste, or over 1 kg of acutely hazardous waste per month.

A review of the RCRA-LQG list, as provided by EDR, and dated 12/09/2014 has revealed that there are 2 RCRA-LQG sites within approximately 0.25 miles of the target property.

RCRA-SQG: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Small quantity generators (SQGs) generate between 100 kg and 1,000 kg of hazardous waste per month.

A review of the RCRA-SQG list, as provided by EDR, and dated 12/09/2014 has revealed that there are 7 RCRA-SQG sites within approximately 0.25 miles of the target property.

CA ENVIROSTOR: The Department of Toxic Substances Control's (DTSC's) Site Mitigation and Brownfields Reuse Program's (SMBRP's) EnviroStor database identifes sites that have known contamination or sites for which there may be reasons to investigate further. The database includes the following site types: Federal Superfund sites (National Priorities List (NPL)); State Response, including Military Facilities and State Superfund; Voluntary Cleanup; and School sites. EnviroStor provides similar information to the information that was available in CalSites, and provides additional site information, including, but not limited to, identification of formerly-contaminated properties that have been released for reuse, properties where environmental deed restrictions have been recorded to prevent inappropriate land uses, and risk characterization information that is used to assess potential impacts to public health and the environment at contaminated sites.

A review of the CA ENVIROSTOR list, as provided by EDR, and dated 03/11/2015 has revealed that there are 35 CA ENVIROSTOR sites within approximately 1 mile of the target property.

State and tribal leaking storage tank lists

CA LUST: The Leaking Underground Storage Tank Incident Reports contain an inventory of reported leaking underground storage tank incidents. The data come from the State Water Resources Control Board Leaking Underground Storage Tank Information System.

A review of the CA LUST list, as provided by EDR, and dated 03/13/2015 has revealed that there are 54 CA LUST sites within approximately 0.5 miles of the target property.

State and tribal registered storage tank lists

CA UST: The Underground Storage Tank database contains registered USTs. USTs are regulated under Subtitle I of the Resource Conservation and Recovery Act (RCRA). The data come from the State Water Resources Control Board's Hazardous Substance Storage Container Database.

A review of the CA UST list, as provided by EDR, and dated 03/13/2015 has revealed that there are 16 CA UST sites within approximately 0.25 miles of the target property.

Other Ascertainable Records

RCRA NonGen / NLR: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Non-Generators do not presently generate hazardous waste.

A review of the RCRA NonGen / NLR list, as provided by EDR, and dated 12/09/2014 has revealed that there are 2 RCRA NonGen / NLR sites within approximately 0.25 miles of the target property.

EXECUTIVE SUMMARY

RMP: When Congress passed the Clean Air Act Amendments of 1990, it required EPA to publish regulations and guidance for chemical accident prevention at facilities using extremely hazardous substances. The Risk Management Program Rule (RMP Rule) was written to implement Section 112(r) of these amendments. The rule, which built upon existing industry codes and standards, requires companies of all sizes that use certain flammable and toxic substances to develop a Risk Management Program, which includes a(n): Hazard assessment that details the potential effects of an accidental release, an accident history of the last five years, and an evaluation of worst-case and alternative accidental releases; Prevention program that includes safety precautions and maintenance, monitoring, and employee training measures; and Emergency response program that spells out emergency health care, employee training measures and procedures for informing the public and response agencies (e.g the fire department) should an accident occur.

A review of the RMP list, as provided by EDR, and dated 02/01/2015 has revealed that there is 1 RMP site within approximately 0.001 miles of the target property.

CA HAZNET: The data is extracted from the copies of hazardous waste manifests received each year by the DTSC. The annual volume of manifests is typically 700,000-1,000,000 annually, representing approximately 350,000-500,000 shipments. Data from non-California manifests & continuation sheets are not included at the present time. Data are from the manifests submitted without correction, and therefore many contain some invalid values for data elements such as generator ID, TSD ID, waste category, & disposal method. The source is the Department of Toxic Substance Control is the agency. This database begins with calendar year 1993.

A review of the CA HAZNET list, as provided by EDR, and dated 12/31/2013 has revealed that there are 10 CA HAZNET sites within approximately 0.001 miles of the target property.

Cleanup Status: NON-OPERATING				

2020 COR ACTION: The EPA has set ambitious goals for the RCRA Corrective Action program by creating the 2020 Corrective Action Universe. This RCRA cleanup baseline includes facilities expected to need corrective action. The 2020 universe contains a wide variety of sites. Some properties are heavily contaminated while others were contaminated but have since been cleaned up. Still others have not been fully investigated yet, and may require little or no remediation. Inclusion in the 2020 Universe does not necessarily imply failure on the part of a facility to meet its RCRA obligations.

A review of the 2020 COR ACTION list, as provided by EDR, and dated 04/22/2013 has revealed that there is 1 2020 COR ACTION site within approximately 0.25 miles of the target property.

EDR HIGH RISK HISTORICAL RECORDS

EDR Exclusive Records

EDR MGP: The EDR Proprietary Manufactured Gas Plant Database includes records of coal gas plants (manufactured gas plants) compiled by EDR's researchers. Manufactured gas sites were used in the United States from the 1800's to 1950's to produce a gas that could be distributed and used as fuel. These plants used whale oil, rosin, coal, or a mixture of coal, oil, and water that also produced a significant amount of waste. Many of the byproducts of the gas production, such as coal tar (oily waste containing volatile and non-volatile chemicals), sludges, oils and other compounds are potentially hazardous to human health and the environment. The byproduct from this process was frequently disposed of directly at the plant site and can remain or spread slowly, serving as a continuous source of soil and groundwater contamination.

A review of the EDR MGP list, as provided by EDR, has revealed that there are 3 EDR MGP sites within approximately 1 mile of the target property.

EXECUTIVE SUMMARY

EDR US Hist Auto Stat: EDR has searched selected national collections of business directories and has collected listings of potential gas station/filling station/service station sites that were available to EDR researchers. EDR's review was limited to those categories of sources that might, in EDR's opinion, include gas station/filling station/service station establishments. The categories reviewed included, but were not limited to gas, gas station, gasoline station, filling station, auto, automobile repair, auto service station, service station, etc. This database falls within a category of information EDR classifies as "High Risk Historical Records", or HRHR. EDR's HRHR effort presents unique and sometimes proprietary data about past sites and operations that typically create environmental concerns, but may not show up in current government records searches.

A review of the EDR US Hist Auto Stat list, as provided by EDR, has revealed that there are 31 EDR US Hist Auto Stat sites within approximately 0.25 miles of the target property.

EDR RECOVERED GOVERNMENT ARCHIVES

Exclusive Recovered Govt. Archives

CA RGA LUST: The EDR Recovered Government Archive Leaking Underground Storage Tank database provides a list of LUST incidents derived from historical databases and includes many records that no longer appear in current government lists. Compiled from Records formerly available from the State Water Resources Control Board in California.

A review of the CA RGA LUST list, as provided by EDR, has revealed that there are 14 CA RGA LUST sites within approximately 0.001 miles of the target property.

US BROWNFIELDS:

Recipient name:	West Sacramento, City of
Grant type:	Assessment
Property name:	205 2ND STREET
Property #:	010-012-04
Parcel size:	.15
Property Description:	Historically the site contained a dwelling unit and out building until sometime after 1915 when the structures were demolished and a levy was built on the site. Since that time, the site has contained a levy that is part of the Sacramento River levy system.

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

US BROWNFIELDS:

Recipient name:	West Sacramento, City of
Grant type:	Assessment
Property name:	319 3RD STREET
Property #:	010-371-03
Parcel size:	.4
Property Description:	The property is a former metal plating facility that has been identified as a seriously contaminated property. The plating shop operated at the property from at least the 1950s until 1986 when a fire destroyed on the buildings at the site. Site investigations conducted at and around the site between 1997 and 2008 revealed highly elevated levels of heavy metal contamination including chromium, nickel and lead.

319 3RD STREET (Continued) **1010735583**

(DTSC-EnviroStor) is an online search and Geographic Information System (GIS) tool for identifying sites that have known contamination or sites for which there may be reasons to investigate further. The EnviroStor database includes the following site types: Federal Superfund sites (National Priorities List (NPL)); State Response, including Military Facilities and State Superfund; Voluntary Cleanup; and School sites.

US EPA Assessment, Cleanup and Redevelopment Exchange System (ACRES) is an federal online database for Brownfields Grantees to electronically submit data directly to EPA.

Environmental Interest/Information System

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Actual: Property name:	FIREHOUSE BLOCK SITE A
26 ft. Property #:	01-371-07, 01-371-08, 010-371-09
Parcel size:	2.5
Property Description:	Property now vacant with concrete pads remaining in place from prior residential use. Some shrubs & trees still remain. Property initially developed in late 1890s & early 1900s for residential use. Property bisected by an overhead freeway/bridge access structure which was reason for removal of residences. Property held in private family trust. Very limited use of less than 0.25 acres as a parking lot for adjacent Firehouse property when used as a police substation - asphalt remains in place.

Status:	Completed - Case Closed
Status Date:	08/24/2012
Lead Agency:	CENTRAL VALLEY RWQCB (REGION 5S)
Case Worker:	DFS
Local Agency:	YOLO COUNTY
RB Case Number:	570326
LOC Case Number:	Not reported
File Location:	Not reported
Potential Media Affect:	Other Groundwater (uses other than drinking water)
Potential Contaminants of Concern:	Gasoline, Diesel
Site History:	The case was opened following an unauthorized release from an underground storage tank system at the subject site. Corrective action is underway as directed by the CVRWQCB. Corrective action may consist of preliminary site investigation, planning and implementation of remedial action, verification monitoring, or a combination thereof. A summary of the site history is available by clicking on either the "Cleanup Status History", "Regulatory Activities" or the "Site Maps/Documents" tab. For a complete site history the case file at the CVRWQCB should be consulted.

Background Info:	The Southern Pacific Transportation Company's (SPTCo) Sacramento Railyard Facility has been in operation since 1865. The site is approximately 240 acres. Inorganic and organic contamination are broadly distributed across a majority of the site. Additionally, liquid waste was historically disposed of in an industrial sewer system constructed over 100 years ago. On June 2, 1988, the Department and SPTCo entered into an Enforceable Agreement. A workplan and schedule for investigatio and cleanup was finalized in October of 1988. Based on historical usage and known contamination the site wa divided into six study areas: Central Shops (CSSA), Central Corridor (CCSA), Car Shop Nine (CSNSA), Lagoon (LSA), Northern Shops (NSSA) and Sacramento Station (SSSA). The Lagoon Study Area contains the former industrial waste water lagoon, an API oil/water separator overflow area, and the former location of a 50,000 gallon barrel oil storage tank. The soil and groundwater are extensively contaminated. Soil contami-

UP, DOWNTOWN SAC - LAGOON (Continued) **S105954434**

	nation includes metals, Volatile Organic Compounds (VOC's), Semi Volatile Organic Compounds (SVOC's) including Poly Nuclear Aromatics (PAH's), and total Petroleum Hydrocarbons (TPH). Groundwater contamination includes metals, VOC's, SVOC's, and TPH.

Background Info:	The Sand Piles Site was the location on the Southern Pacific Transportation Compnay's Sacramento facility at which spent sand blasting grit was stored. Spent sand blasting material is now placed in drums and handled as hazardous waste. Remediation of the Site included the Recylcling of, as a component of asphalt, 2,341 tons of sand. Additionally 897 tons of material was disposed of at a Class I landfill and 236 tons of condrete, wood, and metal debris was disposed of at a Class III landfill. The Department's goal for cleanup was to acheive a level of total lead in the soils below 950 mg of lead/kg of soil. This goal was met. Levels of lead exceeding the STLC of 5.0 mg of lead/kg have been found at and adjacent to the to the previous location of the sand piles. The Department has determined that the remaining contamination is part of a general overall condition at the facility. This contamination will be addressed as part of the overall site investigation and remediation.

Background Info:	The Southern Pacific Transportation Company's (SPTCo) Sacramento Railyard Facility has been in operation since 1865. The site is approximately 240 acres. Inorganic and organic contamination are broadly distributed across a majority of the site. Additionally, liquid waste was historically disposed of in an industrial sewer system constructed over 100 years ago. On June 2, 1988, the Department and SPTCo entered into an Enforceable Agreement. A workplan and schedule for investigation and cleanup was finalized in October of 1988. Based on historical usage and known contamination the site was divided into six study areas: Central Shops and, Central Corridor, Car Shops Nine, Lagoon, Northern Shops, and Sacramento Station. The Battery Shop Yard consisted of battery storage building, associated outside storage yard, and dry well in which waste acid was poured. Soil and groundwater contamination is primarily metals.

Alternate Address:	401 I STREET
Alternate City,St,Zip:	SACRAMENTO, CA 95814
Background Info:	The Southern Pacific Transportation Company's (SPTCo) Sacramento Railyard Facility has been in operation since 1865. The site is approximately 240 acres. Inorganic and organic contamination are broadly distributed across a majority of the site. Additionally, liquid waste was historically disposed of in an industrial sewer system constructed over 100 years ago. On June 2, 1988, the Department and SPTCo entered into an Enforceable Agreement. A workplan and schedule for investigation and cleanup was finalized in October of 1988. Based on historical usage and known contamination the site was divided into six study areas: Central Shops and, Central Corridor, Car Shops Nine, Lagoon, Northern Shops, and Sacramento Station.

UP, DOWNTOWN SAC - NORTHERN SHOPS/DRUM S (Continued) **S105954432**

The Central Shops were used to construct, repair, and maintain locomotives. Results of three soil remedial investigation phases have shown extensive soil and groundwater contamination. Soil contamination includes metals, Volatile Organic Compounds (VOC's), Semi Volatile Organic Compounds (SVOC's), Poly Nuclear Aromatics (PAH's), and Total Petroleum Hydrocarbons (TPH). The groundwater contamination extends south, off-site, to P Street. Off-site groundwater contaminants are primarily chlorinated solvents.
